A Lecture

ON

SYRINGAL HÆMORRHAGE INTO THE SPINAL CORD.

livered at the National Hospital for the Paralysed and Epileptic on Feb. 8th, 1903,

By SIR WILLIAM R. GOWERS, M.D., F.R.C.P. Lond., F.R.S.,

PHYSICIAN TO THE HOSPITAL

ENTLEMEN,—The human frame is the most complex and orate structure known to us. It is not surprising, there-, that its development should sometimes fail to achieve pletion or that this failure should occur in the most orate of all its parts, the central nervous system. Defec- development is found most frequently in the spinal and it is to one effect of this imperfection that I ask attention to-day. The precise defect we are concerned is that which entails the presence of peculiar cavities in cord. Such cavities have been ascribed in some cases to r causes. To this I will refer presently, but it is ain that they are often, and perhaps generally, the lt of a local arrest of the process of development.

on know that the spinal cord is at one stage an elongated of embryonal tissue, having a medial furrow the sides which ultimately close. You know that the closure may to occur in part and that even the closure of the bony al may not take place, with "spina bifida" as the result know—I hope I am not presuming on too much know-ge—that the defect in the bony canal may be slight or absent and yet it may be definite in the spinal cord. may also know that there may be defective development hin the parts that do coalesce. Embryonal tissue persists re its development into nerve structure fails to occur often there is an actual cavity in this tissue. Thus we have cavities where closure has failed to occur with or hout adjacent embryonal tissue or we may have cavities re embryonal tissue has broken down. Those are the ntial facts of what is called "syringomyelia." There be a cavity in the middle line usually continuous with central canal, where should be the posterior medial raphe. s is obviously due to imperfect closure. Or there may a cavity adjacent to the posterior horn, often one on h side, but unequal in extent. These may be continuous h the central canal on one side or on both.

hese lateral fissures in the posterior column are espe-ly important from a pathological point of view. In the cess of normal development a portion of embryonal ue becomes isolated, and remains unchanged, as the tinous caput cornu posterioris. The lateral cavities arently result from an abnormality or imperfection in this cess. All the developmental cavities occur in the posterior central regions of the cord—a fact that is intelligible o this region is the last to attain structural completeness. such cavities, when dilated, may compress and damage anterior horns, with muscular atrophy as the result, and the lateral columns of the cord, causing spastic paralysis he legs It has been maintained of late that similar ties in the spinal cord sometimes result from preceding orrhage, and Schultze[1] has suggested that their origin be minute hæmorrhages in the grey matter caused by ult birth. This is a possible cause, although not yet ed. But their precise origin d[illegible] not concern us now their presence and not their cause with which we have .

e developmental nature of these cavities is often ested by the fact I have mentioned—that they are ered by undeveloped embryonal tissue. It forms a ding layer, sometimes encroached on by erosion when d has long distended the cavity, sometimes consider- increased by a process of growth. Such residual e is prone to increase and its growth is occasionally so considerable as to constitute what is called "gliomatosis"—i.e., a glioma which can be traced to exuberant morbid development of such residual tissue. The word "gliosis" has been applied to it when it does not form a distinct tumour. The normal neuroglia is the remains of this embryonal tissue and gliomata elsewhere have been thought to arise from spots of such residual tissue. It is certain that glioma of the pons—that infiltrating growth which causes great enlargement before it interferes with function—is sometimes connected by tracts of similar tissue with gliosis around a congenital cavity in the cervical spinal cord. That is a pregnant fact. It supports the hypothesis that such tumours may have their origin in residual undeveloped embryonal tissue. It shows us also that these developmental defects may extend up from the cord to the mesencephalon although seldom as actual cavities. We shall presently see the importance of this fact. The symptoms produced by this variable state arise, as I have said, in consequence of the distension of the cavities or the growth of the adjacent tissue. Indeed, some may be due to the absence of the nerve tissue which has not formed. The former generally come on after adult life is reached, but those which are due to simple defect exist from birth. You know the common characteristics of those of the first class, pain, analgesia without anæsthesia, and muscular wasting when the anterior grey substance is damaged. But the symptoms vary in different cases, just as do the cavities, and they are sometimes such as would not suggest their cause Indeed, such cavities are sometimes found when no symptoms can be heard of and we should therefore be prepared for the fact that the symptoms may often be slight and not characteristic. With unsuggestive symptoms we can hardly suspect this cause unless there is the additional evidence of imperfect development afforded by defective closure of the spinal bones, called "spina bifida occulta" Such imperfect closure of the bony canal, with no external tumour, affords ground for suspecting a like state of imperfection in the spinal cord.

Let me tell you of a case in which this evidence was most suggestive A man, 35 years of age, had suffered much pain in the arms for eight years. He was a professional musician. Use of the arms in playing relieved the pain for a time but then increased it and induced also a feeling of powerlessness. When I saw him the pain extended down the inner side of each arm and was especially great in the upper part. Objectively nothing abnormal could be found There were no tenderness and no deficient sensibility of any kind. The only thing discovered was that the right trapezius was a little smaller than the left and presented distinctly less excitability and contraction to both faradism and voltaism in all its parts The case had baffled the medical men who had seen it; by one it was regarded as myelitis The key to what I believe was its nature was this fact. At the bottom of the dorsal spine was a peculiar cicatrix, something like the umbilicus but with furrows running from it a short distance to right and left. On this were a few large hairs, a very suspicious indication. The first two lumbar spines could not be felt; they were apparently absent. The scar had been there as long as the patient could remember and he had been told that it was present at birth. If so it seemed to be a case in which an external spina bifida had sloughed away in utero. At any rate it was clearly a case of spina bifida occulta. This involved a high probability, almost certainty, of a defective spinal cord in that region and we know how often this is associated with imperfect development higher up, with a fissure or fissures. The fact made syringomyelia the probable cause of the pain and we could thus understand why no treatment had had any influence on his suffering. If the assumed nature of the case is correct it is an illustration of the various and dubious symptoms which may be produced by such congenital disease.

But it is not with these cases, with trifling symptoms, that I am specially concerned to-day. I wish to direct your these cavities
f the greatest
d determines
special, perhaps characteristic, symptoms. I have seen several cases in which the peculiar character of the symptoms can be best understood by ascribing them to a hæmorrhage into such a cavity as we have considered. In some other symptoms made this probable.

First, however, let me give to you a fact which proves that this is not a purely hypothetical pathology. I show you sections from a spinal cord in which such syringal hæmorrhage had occurred. A series of the sections are figured in my "Manual of Diseases of the Nervous System" (Vol. I.). A cavity passed from the position of the central canal backwards and outwards along the left posterior horn and extended from the cervical region to the lower part of the cord. Through part of the dorsal region there was a similar smaller cavity on the right side. That on the left was distended with blood throughout. Hæmorrhage into it had apparently commenced in the cervical region for here the cord was so broken up by the extravasation that only a layer of nerve tissue remained outside the blood. It is probable that the blood had escaped into the cavity in this part and had gravitated downwards. After distending the whole cavity the resistance caused the blood to work its way into the spinal cord at the seat of the primary hæmorrhage and to cause death, partly by the local destruction it wrought and partly by the adjacent inflammation it excited, which ascended the cervical cord until all the muscles for breathing were rendered powerless.

---

[1] eitschrift für Nervenkrankheiten, 1903. See also A. Westphal, v für Psychiatrie, 1903.

The case occurred here 25 years ago and the notes are imperfect, but they show certain important facts. The patient was a man, 48 years of age, and, as far as could be learned, he had had no preceding symptoms to suggest the existence of these cavities. The onset was acute but not instantaneous. One evening at his work he found his legs "giving way" but managed to walk home. On the next morning he could not stand and in the course of the day he ceased to be able to move the legs. He did not lose all power of contracting the muscles; this, indeed, persisted even to the end of life, nearly five weeks after the onset. Such an acute development of symptoms suggests myelitis and so do the facts that the man was not temperate and had lately been much exposed to cold and wet. But there were other symptoms which indicated more than inflammation. During the first night he had most painful tingling between the knees and the ankles and this was followed by acute pain in the spine and pain behind the knees. Even when admitted to the hospital three weeks later any movement of the body caused pain in the spine "as if a knife were driven down it"—pain that made him shriek, attended with less sharp pain in the legs as if they were being broken across. Such pain does not occur in simple myelitis; it is a characteristic of hæmorrhage. When admitted, three weeks after the onset, he had lessened sensibility to touch over the legs, but that to pain and to heat was increased, a strange condition hardly known in myelitis. There was flaccid palsy with loss of all reflex action. Weakness of the arms developed during the fourth week of the disease and became complete at the shoulders and elbows, while some movement of the fingers continued to the end. With this loss movement of the thorax failed on the left side (that of the syringal hæmorrhage) earlier than on the right, and was followed by paralysis of the diaphragm and difficulty in swallowing. During the last days of life occasional contraction of the sterno-mastoid and extra-respiratory muscles effected some slight breathing, insufficient to maintain life. He died on the thirty-third day from the onset. Almost to the last he could feebly contract most of the muscles of his legs and the muscles of the hands.

I have told you the lesion that was found: extravasation into a cavity beside the left posterior horn, extending from the cervical region downwards. From the chief seat of hæmorrhage in the lower cervical region, where the blood had passed into the substance of the cord, a little had escaped into the membranes. There was no hæmorrhage upwards within the cord, but there were signs of ascending myelitis, and to this secondary inflammation we must ascribe the later fatal ascending paralysis. The precise relation of the symptoms to the morbid process is not easy to discern, but some important points are distinct. One fact which the case illustrates is that the onset of the symptoms of syringal hæmorrhage may be less sudden than those of hæmorrhage usually are. If the blood escapes into a cavity of considerable vertical extent, there is not much erosion of the cord at the seat of the hæmorrhage until the cavity is filled. In this case it is probable that such erosion did not occur until after the hæmorrhage into the cavity had ceased and that a renewal of hæmorrhage was excited by the removal of the patient to the hospital and this invaded the substance of the cord at the place of least resistance. In the second place the effect of such hæmorrhage on the functions of the cord may be less absolute and less consistent than those produced by a simple tion into its substance. Thirdly, the case shows effect of such a lesion may be increased by myelitis, a slower subsequent process, the danger of should always be remembered.

I have mentioned that the opinion has been by some authorities who have given much attention subject, that many cavities regarded as congenital such, but are the result of hæmorrhage. But the have related shows what care is necessary in concluding a circumscribed space, occupied by blood through a able extent of the cord, was produced by the found in it. It might have been thought that in the hæmorrhage had forced its way down the cord caused the cavity it occupied, were it not for the definite the cavity possessed and were it not for the fissure adj to the right posterior horn which extended through the dorsal region. It was not continuous with the o contained no blood. But it was symmetrical and this makes their congenital nature highly probable—ce believe. Were it not for this second fissure it would been easy to think that the other was actually the fatal hæmorrhage.

We can understand that hæmorrhage may easily into these pre-existing cavities. They are i position and in size and therefore in their vessels. The adjacent gliomatous tissue, the embryonal tissue which surrounds them, seems to be broken down by the fluid they contain. Adjacent are imperfectly supported and may easily give way. over, the gliomatous growth which occurs is vascular may be a source of hæmorrhage. In a case described by Dr. Alexander Bruce[2] fatal hæmorrhage occurred into a gliomatous tumour in the cord co cavities. The tumour was apparently due to local residual tissue, but it was so vascular as to deserve the "angio-glioma." The extent of the resulting extrava will depend upon the size of the vessel and, if the escapes into a cavity, on the size and vertical extent of Lastly, the symptoms produced will vary according force with which the blood flows out and to the se effect of the hæmorrhage. It is important to rememb hæmorrhage may produce its manifestations by de of tissue, by pressure, by slower erosion of the ad structures, or also by secondary inflammation, such as a results from a traumatic process. Thus some effects o condition may not coincide with the primary extravasa but may be developed as this increases or they may slowly follow it.

Let me now mention to you the symptoms of two which are, I think, only to be explained by assuming hæmorrhage occurred into such a pre-existing cavity. perhaps, significant that the diagnosis has to be a inference and not of demonstration. It signifies that rhage confined to such cavities is a less fatal lesion hæmorrhage into the substance of the cord. As we seen from the case I have mentioned the latter may secondary effect; hæmorrhage into a cavity may beyond it, may work into the substance of the as in the case I have mentioned, with far effects than if the extravasation is limited to cavity, as we may assume it was in the cases w have to describe. They differ widely in their but they agree in two features: in the prominen sensory loss and in its peculiar seat and limitation, first case presents a distribution of motor palsy w scarcely possible to explain except on the supposition I advanced. In considering the symptoms remember cavities occur chiefly in the posterior region; hence understand the degree of sensory impairment. Rem also, that a cavity along the posterior cornu, if di blood, may compress the lateral column, and if it forward to the central region it may compress the horn. Remember, lastly, that such hæmorrhage is slowly absorbed; ultimately the extravasation bulk as the disintegrated blood is removed and symptoms due to compression and not to laceration may ultimately pass away to an extent would not be expected from their initial degree would scarcely be thought possible from the long during which their severity is maintained. This seems the lesson of the first case and if it can be trusted it ortant it is to recognise the morbid process It tify hope when otherwise there would be only

1 —A member of our own profession, 40 years after a good deal of worry and a hard day's very cold weather, felt at night a momentary stab in the right side of the head, followed by a peculiar giddiness, objective vertigo, in the dark Although I see nothing he felt as if everything before him sing from one side to the other Then he fell At three o'clock in the morning he woke up to find arm powerless He pinched it and discovered that it insensitive On the next morning it was found to be ly paralysed, and so ned The co I saw e months later Even at first there was no weakness ace or of the leg Sudden paralysis of the left arm, by sudden pain in the right side of the head and s, naturally suggested a cerebral lesion, and it was by the medical men who saw him that there had ombosis of a cortical vessel on the right side of the Such sudden palsy always indicates a vascular upture or closure But there was no heart disease to a source for embolism and cerebral hæmorrhage at of age without renal disease was most unlikely

mptoms, when closely scrutinised, were incompatible sease of the brain The points of distinction are ive A cerebral lesion never causes *complete* paralysis arm without any affection of the face or leg The es are in such contiguity that absolute destruction centre for the arm or the path for the arm cannot ithout such implication of the adjacent regions for and leg as to cause impairment of their function, at for a time Moreover, in cerebral paralysis of the muscles of the shoulder girdle are never completely d In this case the affection of these muscles was ible There was complete loss of power of the s, of the sterno mastoid, and of the pectoralis on the Movement of the head to one side may be at first ed from brain disease but complete paralysis of the uscles never occurs The sterno mastoid is weakened to the paralysed arm not on the same tom, the peculiar palsy of the neck at the condition was due to a lesion of hal cord The affection of sensibility confirmed a striking way There was complete loss of ity in the forearm below the elbow and it was diminished on the outer part of the upper arm ghtly on the inner side The greater loss extended e shoulder and the side of the neck almost to the the jaw and behind almost to the occipital bone, uddenly It also passed down over the level of the angle of the scapula and edge of the ribs everywhere stopping middle line On the face head, and abdomen sensa s normal Such a distribution could not result from l disease From this cause the loss which extended neck would certainly have passed on to the face and d also from the thorax to the abdomen. Thus this early indicated a lesion of the spinal cord The tiveness of the pain in the *right side of the head* was d by the fact that he had been liable to such pain for ears Transient vertigo has little localising signifi and, as we shall see it could be otherwise explained

mystery of a spinal lesion so severe and yet so in effect, damaging the left side of the cord vely and yet not interfering with the right side, have been very great but for another symptom suggested an explanation for its occurrence and also limitation He had a congenital defect of certain ents of the eyes They were habitually directed to not be moved at all to the right of the leed, the left eye was habitually directed y to the outer canthus, and could not be t even up to the mid position, nor could it be moved ds beyond its habitual position Yet it could be moved ly downwards and outwards It could not be moved ls and with this was associated a little drooping of the The right eye could be moved inwards upwards, and ards well, but not outwards at all Thus there was enital absence of movement of both eyes to the right most all movement of the left eye Such a con- life long means a congenital defect of structure upper part of the pons on the left side We know that such defects in the pons may be associated with similar defects in the spinal cord and that in the cord these take the form of syringomyelic cavities or fissures, usually as I have said, with an adjacent layer of gliomatous tissue and often with separate tracts of such tissue Thus, the condition of the eyes revealed the probability of a state of the cord such as might have determined both the occurrence and the limitation of the disease, a congenital cavity into which hæmorrhage had occurred A congenital asssociated defect in the pons would fully explain the peculiar vertigo, since a sudden hæmorrhage into the cord might cause disturbance of function in that part (closely related to the maintenance of equilibrium) especially if the two conditions were structurally connected Three months later the loss of sensation had lessened in degree, it still extended over the same regions, although at the margins it passed more gradually into the normal state The paralysis remained as before, although he could just contract the trapezius and sterno mastoid he could not contract the pectoralis All the muscles had wasted, but only in a moderate degree, and, as at first, there was merely a diminution in electrical irritability, just the same to faradism and to voltaism We can understand this if the anterior grey matter was compressed by the hæmorrhage but not destroyed It would be so compressed if a cavity beside the posterior horn extended forwards to the neighbourhood of the central canal The wrist-jerk was increased and there was some excess of knee jerk, but without weakness of the leg

I have not seen the patient since, but I have lately learned that after two years the power gradually began to return, and that he has since regained fair power over all parts of the arm I am glad to say that absolute confirmation of the diagnosis is still lacking, for he is otherwise in excellent health But there has not been wanting some evidence of the accuracy of the diagnosis You, perhaps know that the peculiar joint disease met with in tabes, with enlargement of the ends of the bones, is also met with in syringomyelia This patient, after the attack of paralysis, had increasing trouble at the hip joint He believed that at two years of age the joint had been dislocated and the displacement reduced, but such an accident would manifestly not explain grave and increasing trouble after mid life Mr C J Symonds took him into Guy's Hospital and operated He found the head of the femur enlarged to twice its normal size and sawed it off The edges of the acetabulum were thickened to twice the normal The patient made a good recovery and has since acquired a most useful new joint The condition presented so close a resemblance to this special arthropathy as to constitute some corroboration of the diagnosis of syringomyelia, in spite of the absence of any change in sensation in the leg As I have said, the great cause of tabes (syphilis) could be quite excluded But another peculiar symptom occurred which may be taken for what it is worth It is said that "phlebitis —i e, venous thrombosis—is more common in the subjects of syringomyelia than in others Whatever may be the value of the assertion this patient had a clot in some veins of the leg on two occasions first soon after the attack of paralysis and again after the operation All things considered, I think we have reason to believe that there occurred in this case hæmorrhage into a syringal cavity and that the evidence is as strong as we can expect to meet with short of pathological proof

Case 2 —In sion is such as to It is that of a mar esis From this the the sisters themsel ome other congenital diseases, notably in pseudo hypertrophic paralysis At the age of 16 years he gave himself a sudden shock by jumping over a box, he felt no immediate effect, but the next morning had lost power and sensation in the legs He slowly recovered fair power of movement but considerable defect of sensibility remained and was still present when I saw him 20 years after the onset During the intervening time he had some attacks of transient swelling of the knee joints, thought to be due to hæmorrhage into them, diathesis Some defect the only motor years from legs intermittent at first, but lately more constant had a troublesome ulcer on one toe which was and when healed was prone to sections from a spinal cord in which such syringal hæmorrhage had occurred. A series of the sections are figured in my "Manual of Diseases of the Nervous System" (Vol. I.). A cavity passed from the position of the central canal backwards and outwards along the left posterior horn and extended from the cervical region to the lower part of the cord. Through part of the dorsal region there was a similar smaller cavity on the right side. That on the left was distended with blood throughout. Hæmorrhage into it had apparently commenced in the cervical region for here the cord was so broken up by the extravasation that only a layer of nerve tissue remained outside the blood. It is probable that the blood had escaped into the cavity in this part and had gravitated downwards. After distending the whole cavity the resistance caused the blood to work its way into the spinal cord at the seat of the primary hæmorrhage and to cause death, partly by the local destruction it wrought and partly by the adjacent inflammation it excited, which ascended the cervical cord until all the muscles for breathing were rendered powerless.

The case occurred here 25 years ago and the notes are imperfect, but they show certain important facts. The patient was a man, 48 years of age, and, as far as could be learned, he had had no preceding symptoms to suggest the existence of these cavities. The onset was acute but not instantaneous. One evening at his work *he found his legs "giving way"* but managed to walk home. On the next morning he could not *stand and in the course of the day he* ceased to be able to move the legs. He did not lose all power of *contracting the muscles; this, indeed, persisted even to the end of life, nearly five weeks after the onset.* Such an acute development of symptoms suggests myelitis *and so do the facts* that the man was not temperate and had lately been much exposed to cold *and wet. But there* were other symptoms which indicated *more than inflammation. During the first night he had most* painful tingling between the *knees* and the ankles and this *was followed by acute pain in the spine* and pain behind the knees. *Even when admitted to the hospital three weeks* [illegible]r *any movement of the body caused* pain in the spine "as [illegible]knife were *driven down it*"—pain that made him shriek, [illegible]tended *with less sharp* pain in the legs *as if they* were being broken across. Such *pain does* not occur in simple myelitis; *it is a characteristic of hæmorrhage.* When admitted, three weeks after *the onset*, he had lessened sensibility to touch over the *legs, but that* to pain and to heat was increased, a *strange condition* hardly known in myelitis. There was *flaccid* palsy with loss of all reflex action. Weakness of the arms developed during the fourth week of the *disease and* became complete at the shoulders and elbows, *while some* movement of the fingers continued to the end. *With this loss* movement of the thorax failed on the left side (*that* of the syringal hæmorrhage) earlier *than on the right*, and was followed by paralysis of *the diaphragm* and difficulty in swallowing. During the last days of life occasional contraction of the terno-mastoid *and extra-respiratory* muscles effected some light breathing, *insufficient* to maintain life. He died on he thirty-*third day* from the onset. Almost to the last he ould feebly contract most of the muscles of his legs and he muscles of the hands.

I *have told* you the lesion that was found: extravasation *ito* a cavity beside the left *posterior* horn, extending from 1e cervical region downwards. From the chief seat of *emorrhage* in the lower cervical region, where the blood had *assed into* the substance of the cord, a little had escaped ito the membranes. There was no hæmorrhage upwards ithin the cord, but there were signs of ascending myelitis, 1d to this secondary inflammation we must ascribe the ter fatal ascending paralysis. The precise relation of the 'mptoms *to* the morbid process is not easy to discrn, but some important points are distinct. One fact hich the case illustrates is that the onset of the symoms of syringal hæmorrhage may be less sudden than ose of hæmorrhage usually are. If the blood escapes into cavity of considerable vertical extent, there is not much, osion of the cord at the seat of the hæmorrhage until e cavity is filled. In this case it is probable that such osion did not occur until after the hæmorrhage into the wity had ceased and that a renewal of hæmorrhage was cited by the removal of the patient to the hospital and this vaded the substance of the cord at the place of least sistance. In the second place the effect of such hæmorage on the *functions* of the cord may be less absolute and less consistent than those produced by a simple tion into its substance. *Thirdly*, the case shows effect of such a lesion may be increased by myelitis, a slower subsequent process, the danger should always be remembered.

I have mentioned that the opinion has been m by some authorities who have given much attentio subject, that many cavities regarded as congenital such, but are the result of hæmorrhage. But the have related shows what care is necessary in conclud a circumscribed space, occupied by blood through a c able extent of the cord, was produced by the *extra* found in it. It might have been thought that in th the hæmorrhage had forced its way down the cord a caused the cavity it occupied, were it not for the defi the cavity possessed and were it not for the fissure a to the right posterior horn which extended through the dorsal region. It was not continuous with the *ot* contained no blood. But it was symmetrical and t makes their congenital *nature* highly *probable*—cer believe. Were it not for this second fissure it woul been easy to think that the other was actually *produ* the fatal hæmorrhage.

We can understand that hæmorrhage may easily into these pre-existing cavities. They are position and in size and therefore in their vessels. The adjacent gliomatous tissue, t embryonal tissue which surrounds them, seems to be broken down by the fluid they contain. Adjacent are imperfectly supported and may easily give way. over, the gliomatous growth which occurs is *vascula* may be *a* source of *hæmorrhage*. In a case re described by Dr. Alexander Bruce[2] fatal hæmorrhag occurred into a gliomatous tumour in the cord cont cavities. The tumour was apparently due to local gro residual tissue, but it was so vascular as to deserve the "angio-glioma." The extent of the resulting extrava will depend upon the size of the vessel and, if the escapes into a cavity, on the size and vertical extent o Lastly, the symptoms produced will vary according force with which the blood flows out and to the sec effect of the hæmorrhage. It is important to rememb hæmorrhage may produce its manifestations by destr of tissue, by pressure, by slower erosion of the ad structures, or also by secondary inflammation, such as a results from a traumatic process. Thus some effects condition may not coincide with the primary extravas but may be developed as this increases or they may slowly follow it.

Let me now mention to you the symptoms of two which are, I think, only to be explained by assuming hæmorrhage occurred into such a pre-existing cavity. perhaps, significant that the diagnosis has to be a mat inference and not of demonstration. It signifies that h rhage confined to such cavities is a less fatal lesion hæmorrhage into the substance of the cord. As we hav seen from the case I have mentioned the latter may secondary effect; hæmorrhage into a cavity may beyond it, may work into the substance of the as in the case I have mentioned, with far effects than if the extravasation is limited to cavity, as we may assume it was in the cases wh have to describe. They differ widely in their symp but they agree in two features: in the prominen sensory loss and in its peculiar seat and limitation, whi first case presents a distribution of motor palsy whic scarcely possible to explain except on the supposition advanced. In considering the symptoms remember th cavities occur chiefly in the posterior region; hence w understand the degree of sensory impairment. Reme also, that a cavity along the posterior cornu, if distend blood, may compress the lateral column, and if it ex forward to the central region it may compress the an horn. Remember, lastly, that such hæmorrhage is slowly absorbed; ultimately the extravasation lessen bulk as the disintegrated blood is removed and symptoms due to compression and not to destr laceration may ultimately pass away to an extent would not be expected from their initial degree would scarcely be thought possible from the long during which their severity is maintained. This seems the lesson of the first case and if it can be trusted it s

d. The object to be kept in view is to pro- cessation of the escape of blood and for this nce is too slight to be neglected and the effect ation for good or ill is too often overlooked. hæmorrhage, whenever it can be endured, the prone of the body should be maintained and if this is le the patient must be kept on the side. If hæmor- curs into the leg the limb is not allowed to hang d if it is even suspected in the spinal cord this ot be the lowest part of the body, as it is when the ies on the back. Indeed, I think that in some cases the sitting posture with the legs depending would likely to promote cessation of the hæmorrhage if ect stillness can be maintained. But remember the ice of posture in all acute affections. If you only ay this lesson you will not have listened in vain, for that you are sure to need in your future work. You er meet with a case presenting such symptoms as syringal hæmorrhage, but you are sure to meet with acute disease of the spinal cord. You will be able stand them better and to deal with them more wisely study of such cases as I have described. You gain real knowledge of any kind that has not far pplications than is at first apparent or may not help n and where you least expect.

An Introductory Address

ON

RELATIONSHIP OF THE MILITARY EDICAL SERVICE TO THE CIVIL PROFESSION.

livered at St. Mary's Hospital on Oct. 1st, 1903,

V. WARREN LOW, M.D., B.S. LOND.,
F.R.C.S. ENG.,

TO OUT PATIENTS AT THE ST. MARY'S AND GREAT NORTHERN
RAL HOSPITALS; JOINT LECTURER IN PRACTICAL SURGERY
AT ST. MARY'S HOSPITAL MEDICAL SCHOOL.

LEMEN,—In these days of image breaking some old possess a curious vitality, and there are few, I that illustrate better the saying that "threatened ve long" than the delivery of introductory addresses opening of our medical winter sessions. Every brings forth its prophecies that lectures, and arly opening lectures, are doomed, and every succeed- r produces its autumnal crop of introductory es; and I have no doubt that if ever Macaulay's alander leaves his vantage ground of London Bridge tures over the disrupted wood-pavement as far as gton he will find evidence of a recently delivered address. The process of evolution has been slow. lly, when lectures played a more important part in cational system than they do at present, intending s would attend the initial lecture of a teacher's course r practically to test his quality. I[illegible] s best and often his discourse decide[illegible] he student attached himself. I say [illegible] ays the school of anatomy was not [illegible]itions [illegible]ly l to the hospital for clinical teaching becom[illegible]ng would then usually set forth the [illegible] urer intended to touc[illegible] vould be added, as th[illegible] ed, a few remarks on [illegible] uestion of the day. [illegible] es were almost purely [illegible] ves, and one cannot [illegible] nearly [illegible], delivered lding a certain chair [illegible] address every October. Much of almost the same [illegible] ssibly, one of the most obvious nged since then. P[illegible]g to the multiplicity of medical has been that owin[illegible]n and provincial, we do not both metropolita[illegible] coming so large a number of e opportunity of we[illegible] the educational year as did at the opening of [illegible]issio[illegible] t one October evening in decessors. We read th[illegible] century Sir Astley Cooper y "twenties" of the last delivered his opening lecture before a class of 400 students; and the chronicler goes on to say: "We never before witnessed so genteel a surgical class; the sight was most pleasing, for they all appeared gentlemen of cultivated manners and good education."[1] Nowadays, the quality goes without saying, but the quantity, alas! is lacking, and he would be a happy dean to day who could contemplate 400 students facing an introductory lecturer. As time went on and a press appeared, giving publicity to medical matters, the delivery of the same address more than once became a matter of some embarrassment and such subjects were usually chosen as the importance of the science of medicine, its value when compared with other professions, and a general outline of its history, till the shades of Æsculapius, Hippocrates, Galen, Celsus, and a host of others must have suffered agonies of apprehension towards the end of September as to what enormities would be attributed to them on the fatal "first" by some bold and imaginative lecturer. Unfortunately, history makes itself but slowly and will only vary within certain limits, so that, driven from this field, the October orator in his desperation resorted to addresses on medical education or on some abstract subject, leaving to his successors an ever-widening range of choice, till I believe a lecture on the subject of Differential Tariffs would not be out of place for an October address.

The subject on which I have ventured to address you this afternoon is one which I believe to be of some considerable importance to us all here and one which the profession and the country at large will have to face seriously in the immediate future; and, therefore, any remarks tending to rouse discussion on this question and to elicit the opinion of those capable of judging deserve careful consideration, even if the views now expressed do not meet with general approval. My subject is, "The Relationship of the Military Medical Service to the Civil Profession," especially dealing with the organisation of the latter in time of war. The Empire has just passed through a war of a magnitude such as it has not experienced for nearly 50 years and within the last three months some of the lessons of that war have been crystallised in an essentially English manner and delivered to us in blue paper covers the result of the labours of a learned commission. There is much food for reflection in these bulky volumes and there is much that especially concerns us as members of the medical profession. Without touching a host of details on which there is much to say and which will doubtless lead to controversy in the future, the salient fact remains that we were not prepared in times of peace in the matter of military medical *personnel* and equipment for a war of the magnitude of that in South Africa, nor do I think that in the present temper of the nation we should be very much better prepared were the same to occur in the near future. As a Secretary of State wrote as far back as 1859, after a similar blue-book had been issued on the subject of the medical arrangements of the Crimean war, "England had always been jealous of standing armies. In their long struggle for freedom the people have found how important it is that they, as well as the Sovereign, should have a hand on the hilt of the Sword of State. But armies once feared by the people on account of their [illegible] account of their pockets. [illegible] we do not like taxes."[2] We do n[illegible] edical unpreparedness That, I [illegible] cause of our want of before t[illegible] it was not the fault of any department, [illegible] e nation. Economy was the motif, and, [illegible] nitarian department of the army felt it most acutely. Those who had the distribution of the mo[illegible] felt, as one witness expressed it, that everything except the trained fighting man could be purchased in the open market on the day; and that is practically what was done; and, as is usually the case, there followed on a period of injudicious parsimony a perfect saturnalia of lavish extravagance.

[illegible] campaign did not break do[illegible] would have us believe, the[illegible] e was much that was obviously defective and might have been remedied, but that they stopped short of an absolute debacle was due to the superhuman exertions of the Royal Army Medical Corps, both officers and men, and to the Anglo [illegible] adaptability of some thousands of civilian medical [illegible], and orderlies who were sent out in lavish profusion, but who, it must be remembered, were absolutely uninstructed in what their duties would be and in the special features of their work. However, out of this evil has come a certain measure of good. We have acquired at this fearful cost very many valuable lessons and there are also certain other definite gains. By this time the man in the street is aware that England has been brought into closer union with her colonies; but another union has taken place, and one that touches more nearly our own profession. We civilian medical men who served in South Africa realise that we have at last been brought into a closer contact with our colleagues in the military medical service.

---

[1] THE LANCET, Oct. 5th, 1823, p

[2] The Right Hon. Sidney Herbert, M.P., [illegible]ew, January, 1859.

The absence of militarism in England has had a peculiarly isolating effect on the soldier. The average Englishman until lately knew little about the army. He knew nothing of its habits, its traditions, or its history. He scarcely knew one regiment from another unless he happened to have a near relative a soldier. They were generically all soldiers to him and he was singularly incurious as to anything further. This isolation, in a less degree, affected the army medical officer. Once he had obtained his commission he practically disappeared from the sight of his civilian contemporaries. In the old days he lived with his regiment and formed new ties and new friendships, necessarily military. The exigencies of foreign service and distant stations kept him out of touch with his old hospital and he seldom had the companionship of members of his own profession or the opportunities of listening to, or joining in, the technical discussions of a medical society. As a result he felt himself to a certain extent cut off from his civilian colleagues and he practised his profession in his own way, only conferring with his military *confrères*, till there grew up an idea among both civilian and military medical men that in some mysterious way the practice of medicine, surgery, or hygiene in the army differed from that in vogue in the world at large, and that the soldier, both individually and in the aggregate, differed in his metabolism and the products thereof from the civilian. It is not difficult to understand how this isolation originated when we remember our national characteristics and the history of our Army Medical Service.

It would serve no useful purpose to go back further than he regimental surgeon, who is practically coeval with the ormation of regiments, though it is interesting to learn that n the reign of Edward II. there was a chirurgeon with very 1900 men, whose pay was 4*d.* a day in addition to hich he had the privilege of shaving the soldiers.[3] But the ory of the Army Medical Service practically dates from regimental surgeon; he held the Sovereign's commission hich, in the early days, he bought in the same way as did his regimental colleagues and he was as much an integral part of the regiment as was the colonel. Later, somewhere n the early half of the eighteenth century, he received an assistant—the surgeon's mate—but the latter was only a warrant officer and did not receive a commission until 1796 when he was styled an assistant surgeon. The regimental surgeon was responsible apparently to his military superiors for the medical care of his regiment and besides his pay of 6*s.* a day he had an allowance proportioned to the strength of the corps for medicines, hire of hospitals, and the medical expenses of detachments and recruiting parties. On expeditions and elsewhere groups of regiments apparently formed hospitals which were under the administration of the regimental surgeons; that these hospitals were sometimes very effective is instanced by a report on the hospitals established in the Low Countries in 1748 for the troops under the Duke of Cumberland. These hospitals were said to be a model of medical administration. "The patients had separate and clean beds, frequent changes of linen, and were attended by well trained female nurses, while hospi[illegible] keepers and clerks acting under the surgeons furnished [illegible] requisite with promptness and regularity."[4] A lengthy [illegible] respondence took place between the Duke of Cumberland and he home authorities with reference to the expenditure incurred in maintaining this establishment and the official mind had certainly not then grasped the fact that the nation had incurred a certain responsibility towards the sick and wounded soldier.

These apparently effective arrangements are in marked contrast with those of the ill-fated Walcheren expedition over 60 years afterwards when in less than eight weeks, within 100 miles of England, out of 40,000 men 7000 from fever and over 14,000 were wrecked in health for remainder of their lives. Although the medical ments of this expedition were of the crudest des[illegible] and totally inadequate the responsibility of this mortality rests rather with those answerable for the [illegible] than with those on whom the medical arrangements devol[illegible] A well-known stanza aptly summarises the history of whole campaign:—

> "The Earl of Chatham, with his sword half drawn,
> Stood waiting for Sir Richard Strachan;
> Sir Richard, longing to be at 'em,
> Stood waiting for the Earl of Chatham."

The earliest trace of a distinct administrative organi[illegible] is said to date from 1756, when Lord Barrington, as [illegible] for War, was directed to establish a hospital board for administration of the medical service of the army, [illegible] intended to take the field, "in order that under its di[illegible] this part of the military service (including medicines, [illegible] stores, and other requisite provision for the sick) might carried into execution with ability, regularity, and despatch. Mark you! "with ability, regularity, and despatch"; was the mandate 150 years ago.

It was by a member of this board that John Hunter appointed in 1760 as a staff-surgeon to the expedition Belleisle and again in Portugal in 1763. In 1790 succeeded Mr. Adair as surgeon-general and [illegible] general of regimental infirmaries. Later, a physician-g[illegible] was appointed and the inspector-general of [illegible] infirmaries was made a separate office. There were established a dual system and a dual control, the [illegible] board under the surgeon-general being responsible for appointment of staff-surgeons and physicians and [illegible] mates to the army and also for the proper equipment maintenance of what were known as general h[illegible] while, to a certain extent, independent of this control, the system of regimental surgeons and regimental h[illegible] That this gave rise to acrimonious disputes chiefly as to bestowal of patronage one has only to read the [illegible] ence of the time to ascertain. By a Royal Warrant, 1798, the surgeon-general's duties were extended comprised the election of all staff-surgeons, regim[illegible] surgeons, and assistants, and the formation of medical staff of every expedition which left the [illegible] At the same time the board was dissolved and three officers comprising it acted separately, each distinct duties and patronage assigned to him and being held responsible for his own acts. A Mr. [illegible] Keates, a surgeon at St George's Hospital, succeeded Hunter as surgeon-general and his conduct during his [illegible] of office was somewhat severely animadverted upon [illegible] Commission of Military Inquiry held in 1807. This inq[illegible] and the really very able defence of Mr. Keates, pu[illegible] under the title of "Observations on the Fifth Report [illegible] Commissioners of Military Inquiry," 1809, is a most [illegible] source of information to anyone who is interested in military medical history of this period. A most int[illegible] personage, whose existence is brought into [illegible] prominence by this commission, is a gentleman styled apothecary-general who, though not a medical man, a Royal patent to supply the army with drugs and [illegible] ments. His emoluments were 10*s.* a day and he also [illegible] the right to make a legitimate profit on the goods [illegible] The commission estimated this profit at something 30 and 40 per cent. on the capital invested, but apothecary-general's estimate was the more modest 13 or 14 per cent.; in either case, when we consider bills amounted in part to [illegible] to between £60,000 and £70,000 per year office [illegible] appears to have possessed very solid a[illegible] tages. [illegible] certainly only 10, probably as the result of the findings of commission. In 18[illegible] the posts of surgeon-general and ph[illegible] general were abolished and a director-general of [illegible] was appointed, with two principal inspectors of [illegible] assist him, and with a few unimportant changes this [illegible]ment lasted until the time of the Crimean War.

It will thus be seen that in the earlier history of the Medical Service the highest administrative posts were [illegible] to civilians and that the regimental surgeons' chance[illegible] promotion were few and precarious. Sweeping [illegible] were made in 1858 as a result of a commission, of Mr. Sidney Herbert, afterwards Secretary of State for [illegible] was a member. With the more recent changes, again result of the report of a Royal Commission, you are [illegible] niliar The status and pay of the Royal Army Medical officer have been improved, opportunities for study- and, what is of even greater import- ages of their career officers may be in civil hospitals It is to advances direction that we must look in the future for improve- in the Army Medical Service and it will be by these that the civil and military branches of our profession e brought into closer union But the establishment is oo small, even in peace, and in war, I am told, it would o the addition of about 500 medical officers before three corps could take the field with their proper medical *nel* It is obvious that no Chancellor of the Exchequer ever agree to such an increase except in a national gency, nor is there necessity for such an establishment t to meet the requirements of a great campaign

[5] Clode's Military Forces of the Crown, vol. ii., p. 463.

he true lesson of the war, in our opinion, is that no ry system will be satisfactory which does not contain s of expansion outside the limit of the regular forces of rown, whatever that limit may be "* These words of the issioners, intended to cover the whole military system, with peculiar force to its medical service. Unlike any branch of the service the medical department possesses erve for war of *personnel* already trained in every pro- nal requirement There was, I believe, never any real lty in obtaining civil medical aid during the late war civilian surgeons were sent out by the War Office and oes not include numbers locally engaged in South Africa staffs of the various civil hospitals and the excellent al units sent with

untrained as regards that amount of which is bound to fall to the lot ith an army in the field The result hat in a great number of instances there was a division oour, the purely professional work falling to the civilian, on the regular officer devolved the drudgery of admini- on In the future I understand that much of the admini ve detail will be rendered less cumbersome and more, t, will be handed over to some other than a Royal Army al Corps officer, but of what is left, though of neces n the higher ranks it must remain with the regular , in the lower it should, I think, be more evenly dis ed between the active and reserve members of the e This should be done, if for no other reason, in to obviate the comparisons between members of the profession that were freely made by laymen in South

feature of the late war was improvisation We have the authority of the commission that this ailment ed the strategy, the organisation, and the equipment ghout the whole service, while it was obvious to one interested that this was the main obstacle to t success of what I may term the mobilisation of the al reserves Almost any system of organisation, had isted in 1899, would have produced a body of ns selected with more judgment than could possibly ercised in the wild rush that took place at the com- ement of the campaign Almost any system would secured men who would have been to a certain extent sant of what was required of them beyond their purely ical work and who, in many cases possibly, would known something of those with whom they were ned to serve, with the result that a fewer number would been required and so considerable expense saved to tate, while the work of the remainder would have more even, more effective, and would have been rmed more in harmony with the traditions of their gues in the regular service It thus becomes almost a of anyone who by some chance has had opportunities dying this matter to assist in formulating a scheme would tend to prevent the recurrence of the unprepared- hat existed in 1899 This must be my excuse for bring- e matter before you this afternoon In the search for a scheme of organisation one naturally turns to the m of other nations There is a prevailing belief every able bodied German has in his possession a on which are inscribed his exact orders with regard ndezvous and equipment in the event of mobilisation her this be so or not the initial difficulty in comparing the military institutions of continental nations with those of England is the system of universal service On the continent there is not that distinction between the military and civilian branches of the profession which exists here Practically every civilian medical man has once been in the army and would merely revert to his former position in the event of war, while in times of peace both work side by side in the large state hospitals In Russia a large part of the civilian practice is in the hands of the military medical officers and their military hospitals would appear to play almost the same rôle that our large voluntary hospitals do in this country Any proposed scheme therefore, must be elaborated with special reference to the peculiarities of our voluntary system of military service and must also keep in view the fact that the civilian in England is absolutely unacquainted with military organisation and even the minimal amount of administrative detail that is essential in the daily routine of military life

There are, I think, certain main principles which should be observed in formulating any scheme Firstly, that any organisation of the civil medical profession for war must have as its framework the Royal Army Medical Corps If the simile did not lend itself to misinterpretation I would like to suggest that the civilians should form the soft parts of a body of which the Royal Army Medical Corps would be the skeleton It has been suggested that the various medical schools should each organise a medical unit ready to take the field but I feel convinced that military units organised and administered by civilians entirely are neither economical nor really effective, and without in any way wishing to depreciate the work done by the civilian hospitals in South Africa I cannot but think that in future the care of the sick and wounded would be more economically provided for by one really effective administration than by the irregular efforts of private enterprise, however well intentioned, and I would suggest, though it is possibly outside the scope of my subject, that the efforts of the charitable should be rather directed towards the provision of such luxuries and comforts or aids to convalescence as a State service could scarcely be expected to provide In this we could not do better than borrow the German plan of appointing a commissioner whose duty it would be to organise such efforts in order to prevent waste and overlapping The second principle is that any civilian absorbed into the Royal Army Medical Corps for the purposes of a war should be, as far as possible, indistinguishable from the regular members of the corps This is not the time to discuss the question of army rank for medical men We must accept the system as we find it and since the Royal Army Medical Corps officer has rank, so must the reservist, if we wish to avoid some of the anomalies of the late campaign Thirdly, in a profession such as ours, in which the environment of the individual—especially of the young individual—is constantly changing we ought not to extend the period of liability for service for longer than a year at a time This principle of an annual register I consider very important Fourthly, there must be some graduation of the civilians selected In the late war there were only two grades—consultants and civil surgeons, as they were called There were nine of the former and, as I have said, over 1000 of the latter In the last class were all degrees of excellence and the reverse—the brilliant student and possibly from the same school, his friend the chronic, the youth just qualified, and men, some of whom had from 10 to 15 years' experience behind them All were equal, all were asked to perform similar tasks, and there was seldom any selection exercised of men for work for which they appeared especially adapted It is wonderful that such a want of system should have obtained even a semblance of success This graduation should, I think, be based as far as possible on professional standing and attainments Lastly, it is important that each medical reserve officer, as we may call him, should know, within reasonable limits, the unit to which he would be attached on mobilisation He would then have some idea of the circumstances in which he would serve, and in many cases, as I shall show later, he would have had some opportunity of forming the acquaintance of those with whom, in the event of a campaign he would be associated The system of army corps lends itself particularly well to this arrangement and there seems no reason why each reserve officer should not be attached to a certain army corps, and in many cases to a particular unit, and not be merely one of a list of names at the War Office for general service

---

eport of the Royal Commission on the War in South Africa, 1903

These, then, are the main principles. 1. Organisation with the Royal Army Medical Corps as a framework. 2. For the medical reserve officer temporary rank equivalent to that of the regular Royal Army Medical Corps officer. 3. An annual register. 4 Graduation according to professional standing. 5. Appointment to definite army corps and if possible to units.

Three grades of professional standing suggest themselves. *A.* The class to which the civil surgeons in the late war mainly belonged, that is to say, men within the first two or three years of their qualification. In this case preference as far as possible would be given to those who had held *resident appointments* in any hospital, and of these between 300 and 400 would be required for three army corps, though the actual number called out in any campaign would naturally depend on its nature and duration. *B.* Members of the junior honorary staff, either medical or surgical, of the metropolitan and provincial hospitals. Certainly in another war we should have to realise the importance of the trained physician. In South Africa we had far too few, but in the stationary and base hospitals a few more men of the class to which the assistant physicians of our London and provincial hospitals belong would have been of the greatest value. With regard to his colleague, the assistant surgeon, his place would be in what in foreign armies are termed the field ambulances. In these days of specialism, however much we may regret the fact, it would appear difficult for a man to become a skilled operator unless he has devoted a considerable proportion of his time to the practice of surgery to the partial exclusion of other branches of his work. Professor A. Ogston, in his evidence before the commission, very clearly brings out this point. "Our operations nowadays," he says, "are pieces of very high art, which a man acquires by daily training. He comes to use his fingers like a conjuror uses his and does things with his hands that have become a habit with him to do, but which at first are a little difficult and require technical skill. If a man has not that daily practice he may know the theory most perfectly, he may be a most able and intelligent man, and yet he will not do such good technical work as the perhaps less able man who has had this practice."[7] The exigencies of general practice and the varied nature of the Royal Army Medical Corps officers' work prevent many men from acquiring this skill; but there are in the Royal Army Medical Corps skilled operators who have had opportunities of extensive practice in such big hospitals [illegible] Woolwich and Netley and in some of the larger [illegible] of India. It is to supplement, and not to [illegible], men like these that I would call up Class "B." [illegible] would consist of a few of the heads of the profession, both medical and surgical, and with them I would include at least one eminent pathologist. These gentlemen would be attached to the large base hospitals as presenting to them the greatest spheres of usefulness and they would also be present for general advisory purposes.

The experience of the South African war has taught us that there is little difficulty in procuring men *during a campaign* and I think, therefore, that a comparatively small inducement would keep the register of each class full during times of peace, while the justification of the extra expenditure involved would be the enormous saving of money effected by instituting an organised plan for a hasty improvisation at the outset of a war. Bearing this in mind, I would suggest the following details.

Class A.—During their year of service in the medical reserve, the members of this class would undergo a month's training, if possible, in the field. For this they would receive £1 per day. In the event of mobilisation each would be attached to a unit in a certain army corps, with the pay, allowances, and temporary rank of a lieutenant of the Royal Army Medical Corps. In the event of their re-enlisting for a third period of service they would on mobilisation receive the pay and rank of a captain of the Royal Army Medical Corps. I do not think that we could expect to keep this class on the register for more than four or five years from qualification, as they would then have settled down into practices which it would be difficult for them to leave.

Class B.—It is with this class that the greatest difficulty arises, as they have all fixed positions and responsibilities from which it is difficult for them to escape for any lengthy period. However, recent experience has shown us that in a national crisis either a feeling of patriotism or a spirit of adventure took many such to South Africa, while institutions like our hospitals exhibited considerable public spirit in keeping their appointments open for them during their absence. About 50 of these would be required for three army corps, with their equivalent base hospitals and lines of communication; and as this number would be distributed over England, Ireland, and Scotland, it could not be said to deplete the staff of any one hospital. A small retaining fee would have to be paid to the members of this class and, bearing in mind how occupied is their time, I would make the question of training optional. In many instances members of Class B would already have received training in Class A. On mobilisation each would proceed to a definite unit, with the style of a major of the Royal Army Medical Corps and with the pay and allowances of the senior members of that rank. The period of liability to service would again be a yearly one, but as an inducement to re-enlistment and to training I would suggest that, after three periods of enlistment with training, the officer would, on mobilisation, take the rank and pay of a lieutenant-colonel.

Class C.—For this class no adequate recompense could be made during times of peace for a lien on their services. But it would necessarily be a limited class and would, I think, be considered a position of some honour. In the event of mobilisation each would take the pay and rank of a surgeon-general. I have said nothing of the Royal Army Medical Corps Militia and Volunteers, as I consider these belong to their own services and would probably themselves require a system of expansion such as I have outlined for the regular army. In the event of militia or volunteers proceeding abroad for active service they would take their own regimental medical officers and bearer companies, but would probably rely on the regular service for the remainder of their medical requirements. The question of a medical service for home defence would be, no doubt, simplified by the fact that there would be in the event of invasion compulsory service for all of us.

Gentlemen, such is the rough outline of a scheme for organisation of the civil medical profession in time of war. I feel that it possesses many imperfections, but as a foundation on which some workable scheme might be based I believe it to be sound. I do not flatter myself that it is not open to criticism. I can hear the cynic ask, "Why pay every year for what we can obtain for very little more when the occasion arises with always the possibility that such an occasion may never arise?" This has ever been the attitude of Englishmen and that it has been a false economy one has only to read the reports of Royal Commissions from their earliest inception to learn. And, gentlemen, I believe I have your sympathy when I say that it is not merely a question of economy and that at least we owe it to our sick and wounded countrymen that the medical service in time of war should be carefully organised and as effective as it is possible to render it.

Gentlemen, it is my pleasing duty this afternoon to offer a hearty welcome to those of you to whom this is the opening session of your professional career. I would that my welcome embraced a larger number. It is said that an old surgeon, remarkable for his bluntness of speech as for his eminence as a teacher, exclaimed one 1st of October on facing his crowded class, "Egad! What will become of you all?" I cannot but think that if the old gentleman were to appear now at the opening of the winter session of any of our medical schools his exclamation would be, "What has become of you all?" But the situation has, at least, this consolation for you, that you are not joining an overcrowded profession. It is not, however, only into the ranks of our profession that I welcome you to day; it is more particularly to this medical school of St. Mary's Hospital. The selection of a medical school is a serious event in the life of a young man, but I know I have the concurrence of all in this room when I say that yours has been a wise choice. I have yet to meet the St. Mary's man who regrets the selection of his *alma mater* and I sincerely trust that he will not be found among you newcomers to-day. It would, I believe, be breaking absolutely with the traditions of the past if I did not on this occasion tender you some advice; though I feel that this would come more appropriately from one of my older colleagues. Possibly, however, the experience of one who has but lately traversed the path you are now approaching may have a value of its own. My advice to you is: Learn to be practical. Learn to do things, rather than how to do them. Many epigrams have been levelled at what is popularly known as the practical man: "He is one who practises the errors of his predecessors"; or, as I have heard it wittily said in this room, "The practical man is one who does only things for which he doesn't know the reason." To this, I suppose, the natural corollary is: "That the theoretical man is one who only knows the reasons for things he cannot do." But there is not this opposition between theory and practice. "Each to a certain extent supposes the other. Theory is dependent on practice, and practice must have preceded theory." Hitherto, in the case of most of you, your education has been based on what are known as "the Humanities"—that is, on a study of the writings and actions of bygone men—the best basis of a liberal education. Now you will have an opportunity of studying Nature herself, of acquiring a knowledge of things as opposed to a knowledge of words. See that you do not neglect the opportunity. Every day learn to do something, whether it be to find a nerve or artery in the dissecting-room, to conduct a physiological experiment or a chemical test, or even to dispense a bottle of medicine. Do not be satisfied with a book description as to how it should be done. Learn to do it. In many cases the mechanical process is tedious and would appear to you a waste of time, but let me assure you it is not. You are unconsciously training other faculties hitherto more or less in abeyance. Your knowledge has till now reached you through the eye or the ear as the written or spoken word. You will now be cultivating other channels of perception, as the sense of touch, while the old routes will be opened up to the appreciation of actual natural phenomena in addition to the previously expressed opinions of others. Learn to do things and your previous education and natural curiosity will insist on the reasons for your doing them. Now is your opportunity. We are all always students, but there are seasons in the pursuit of knowledge as in the life of the planet and this is the springtide of your studentship, and it is all too short.

---

> "Alas! that spring should vanish with the rose:
> That youth's sweet-scented manuscript should close."[6]

See that when you turn the less fragrant pages of advancing middle age you do not, like many of us, have reason to regret lost opportunities of this the springtide of your student life.

Abstracts
OF
INTRODUCTORY ADDRESSES
DELIVERED AT THE
MEDICAL SCHOOLS
AT THE
Opening of the Session 1903-04.

YORKSHIRE COLLEGE, LEEDS.

INTRODUCTORY ADDRESS ON THE MEDICAL CURRICULUM BY E. A. SCHÄFER, F.R.S., LL.D. ABERD., PROFESSOR OF PHYSIOLOGY AT THE UNIVERSITY OF EDINBURGH.

AFTER a few introductory remarks Professor Schäfer went on to say that the object of his address was not so much to place before his audience an ideal at present impossible of attainment as to offer practical suggestions regarding the manner in which a medical curriculum might be planned out in actually existing circumstances. In the first place a university degree in medicine should invariably be a sign of higher attainments than a mere qualification to practise. Medical degrees of the new Leeds University would, he assumed, offer a real distinction and indicate a fair amount of scholarship, but he considered that if as much time were to be devoted to the acquisition of a knowledge of French and German as is given to that of Latin and Greek the result would at least be the acquisition of knowledge which would in nine cases out of ten prove a
man's subsequent career. Most
case if that career were to be the
would, he thought, be even more difficult to obtain a general introduction of the teaching of natural science than of modern languages into secondary schools in the place of a large part of the time now occupied by classical studies. It was appalling to think that many people who passed as highly educated had absolutely no knowledge of any of the sciences except perhaps mathematics. They knew nothing regarding the structure and mechanism of any plant or animal and least of all of the structure and mechanism of their own body. Nature was to them a sealed book and the general fact remained that the ignorance, not of the populace alone, but of the so-called educated classes regarding all matters relating to science was appalling. Professor Schäfer went on to say that as a subject of general education a knowledge of the sciences was an absolutely essential preliminary to the study of medicine and that because such knowledge was not imparted in our schools it had become necessary to incorporate into the medical curriculum, and in so far to burden it with, courses of preliminary science. The rules of the General Medical Council stated that no course of instruction which had not been attended subsequently to registration as a medical student should be permitted to count in fulfilment of the requirements as to science courses necessary for qualification. This regulation was, as they were doubtless aware, being at the present moment defied by the Royal Colleges of Physicians of London and Surgeons of England. These bodies had his entire sympathy in the action which they had taken an
students as it at present stood
the teaching of science in schoo
advocate of the relegation of the
sciences of the medical curriculum to the school period but at present this was impossible. He trusted that the new university would do what lay in its power to promote this reform—that is to say, teaching of science in schools.

Anatomy and physiology, especially physiology, could only be understood by those who had previously acquired a knowledge of these preliminary sciences and the knowledge of physics and chemistry required for the study of physiology was not a mere smattering but should be a very accurate knowledge of certain parts and a good general knowledge of the whole. At present the preliminary sciences were supposed to be overtaken in the first year of the medical curriculum and therefore four years more remained. How were these to be apportioned and what was to be the order of study? The subjects to be mastered during these four years were multifarious and might be divided into three groups, the first of which included anatomy and physiology, the second pathology and pharmacology, and the third medicine and surgery. Anatomy and physiology should certainly be mastered before the study of surgery and medicine was entered upon. He doubted whether in any medical school in this country a sufficient amount of time was given to the practical study of physiology and he was convinced that more benefit would be obtained from working almost wholly at physiology unfettered by any other study, except such a cognate subject as anatomy, for an entire year than during two years with the interpolation of other subjects. Professor Schäfer then continued:

Supposing the way to be cleared by the courses of anatomy and physiology having been completed and the examinations in these subjects passed the student is equipped for the study of pathology and pharmacology and may also begin to work at medicine or surgery in the wards. Of these two I would myself give the preference to medicine as fitting in better with the study of pathology and pharmacology. Besides, it is for various reasons undesirable that the work of the pathological laboratory and attendance in the deadhouse should be concomitant with attendance on operations and the dressing of surgical cases. It is, I know, an almost universal practice to take dresserships in surgery before clerkships in medicine, this being, I presume, one of those traditional usages which die hard. But I know of no valid reason for the practice and I believe the sequence pathology, medicine, surgery to be better. The exact arrangement of the other subjects belonging to the final of the curriculum matters less. Some of the special subjects may be taken earlier, others later. The relative importance of these special subjects is a question about which, as about many others connected with the curriculum, there is by no means a consensus of opinion. But I think that most would agree that it is undesirable to expect as much time to be given to the teaching of such subjects as midwifery as to medicine, to pharmacology as to pathology. Materia medica in the strict sense ought not be part of the curriculum. If a man intends to be a chemist as well as a medical practitioner, he should hold the pharmaceutical diploma. A knowledge of the raw materials of pharmacy is of no value to the student As a rule it is crammed up for examination and speedily forgotten. But a scientific acquaintance with the action of drugs under both normal and abnormal conditions is quite another story and pharmacology must in future have its due position in the medical curriculum and may very conveniently follow physiology of which it is in a sense an extension. As with all other practical subjects, the teaching in pharmacology should be largely of a practical nature. Lectures upon practical subjects are of much less value than practical work in a laboratory: they at least can be replaced by reading; that cannot. It is true that here and there one meets with a lecturer who has the faculty of imparting information in a manner which makes it stick in the brains of his hearers and here and there with a student who can retain more of a subject from the hearing of a lecture than from the reading of the same subject in a text-book. But these cases are rare. More sound knowledge of almost any scientific subject can be obtained within a limited time—and the time devoted to medical studies is very limited—by properly directed reading, accompanied and illustrated by thorough practical work and numerous demonstrations, than from any course of lectures however long. Fortunately the tendency of the present day is to encourage the development of the practical side of teaching. But it is often forgotten in doing so that unless time is found for the practical courses by cutting down the number of lectures the hours of work become unduly prolonged. The number 100 for a course of lectures seems to be a sort of fetish in many universities, as if there were a special virtue in that number or some multiple of it. In these days of good text-books lectures have largely lost the importance they formerly had. Yet we find the newest university, that of Birmingham, the medical curriculum of which is planned in many respects on excellent lines, requiring two attendances on complete courses of lectures on anatomy, medicine, and surgery—no less than 600 lectures on these subjects alone! This, gentlemen, is one of the failings which I would have you avoid.

---

[6] Rubaiyat of Omar Khayyam, lxxii.

Let us briefly consider the order and place of the examinations. Examinations are necessary evils; it is not possible, I believe, to devise any means of testing the knowledge of candidates for a medical degree which is to confer a diploma to practise to which far more important objections could not be urged. Nor can the same objection be taken to practical as to written examinations. A sound practical knowledge cannot be crammed: it must be acquired by actual experience. But in most subjects a practical examination is insufficient, because it is rarely possible to cover enough ground in the available time. Nevertheless, the practical side of the examination should be made to preponderate, for it is the best test of real knowledge. Account may also be taken, as is done in the Birmingham University, of the manner in which the work of the practical courses—including, of course, the clinical courses—has been performed. With this combination a fair estimate of the capabilities of the student could in all probability easily be arrived at.

To understand the existing examination system the manner of its development must be borne in mind. In the beginning certain persons or collections of persons (corporations and universities) were privileged to ascertain the qualifications of those who desired to practise medicine The candidates were not required to submit evidence of having passed through any particular course of study but were expected to satisfy those to whom the above privilege had been accorded or ultimately their nominees—whom we should now call the examiners—that they possessed an adequate acquaintance with medicine, surgery, and the preparation and action of drugs. The candidate was always apprenticed to some practitioner—himself a graduate or licentiate of one of the corporations—who gave the necessary instruction, which might be, and ultimately usually was, supplemented by attendance at a private school of anatomy as well as in the wards of a hospital. There was for a long time but one examination, all the subjects examined on being taken at one sitting. You will find an amusing account of such an examination, evidently taken from the life, in "Roderick Random." Precise knowledge of detail was not expected, or did not exist, and the effort of memory needed to recall the various subjects of the examination would not therefore be great. But as knowledge of things medical became more extensive, and especially after it had begun to be recognised that a regular sequence of instruction was necessary, more defined courses of lectures began to be prescribed, and it was found convenient to subdivide the subjects of examination, and to hold this in two parts at definite intervals; anatomy, with a little physiology, being the main subject of the first part, and medicine, surgery, and midwifery those of the second. It is along these lines that the evolution of medical examinations has proceeded. There is a constant tendency to subdivide, and in subdividing to get past the earlier subjects of the curriculum before proceeding to the later ones. It is now usual in many universities to examine first of all in the preliminary sciences of chemistry, physics, and biology—the last again being often taken separately; secondly, in anatomy and physiology, with materia medica thrown in; thirdly, in pathology; and lastly, in medicine, surgery, and midwifery.

Along the same lines it appears to me the evolution of the examination system will continue; indeed, I see no sufficient reason why the process of subdivision should be confined to groups. If a student has attended the prescribed courses upon any subject, why should he not be allowed to present himself for examination in that subject? There is, I know, an impression in some minds that the taking of subjects in this way has a tendency to cheapen the degree. That it will tend to render a degree easier of attainment I am prepared to concede and to my mind that is a very strong argument in favour of the adoption of the plan. But that it will tend to lower the standard of knowledge required for the degree I altogether deny; on the contrary, it will raise that standard, for a student would certainly be better able to master one subject at a time and the standard of examination in each subject might easily be higher than with the group system. Even under this system there has grown up a tendency in many quarters towards disintegration of the groups. Thus in the University of Edinburgh and in other universities which might be named, although the subjects which are grouped together under the headings of first, second, third, and final examinations are supposed to be taken together, a large amount of latitude is permitted with regard both to the deferring of certain subjects of a group and to the acceptance of a subject in which a sufficient standard is judged to have been attained, even when the pass standard has not been reached in other subjects for which the student presents himself at the same time for examination. Thus for the so-called second professional examination, the subjects of which are anatomy, physiology, and materia medica, a student may not only defer presenting himself in materia medica, but may be credited with a pass in only one of the other two subjects of the examination—may, that is to say, pass in anatomy alone or in physiology alone. It would, I think, be better to take a step further and to permit the student to present himself in the one subject only. This, indeed, he sometimes does in an irregular way—riding for a fall in anatomy, for example, in order to get through his examination in physiology, but he thereby incurs the stigma of having failed in the subject which he had not really prepared for and which he had no idea of passing.

But it might be argued that in many cases two or more subjects are so interdependent that from the educational point of view it would be a bad arrangement to allow them to be taken independently. This argument applies more strongly to anatomy and physiology than to any other of the subjects in the curriculum. Physiology, at any rate, cannot be properly studied without a previous knowledge of anatomy. This anatomy need not, however, necessarily be human anatomy, for the previous study of comparative anatomy is all that need be required for the understanding of physiology—which is, in fact, very largely comparative physiology.

If the subjects of the curriculum were directed to be taken in regular sequence, the principle being as much as possible preserved that every subject is disposed of—as regards both study and examination—before the next subjects are attempted, I venture to think that a much more thorough knowledge of each subject would be attained with far less strain on the mind of the student. Above all there should be no long interval of time between attendance on the courses of study and examination in a subject. The examinations should come whilst the student is fresh from study, for it is impossible to keep up indefinitely the details which are demanded in examinations, and the deferring of the examination often leads to neglect of work during the course of study, followed by a feverish attempt to cram up the subjects during the few weeks before the examination We have experience of this in Edinburgh where the students take out their courses of physiology and practical physiology—including histology—during the second year but are not permitted to present themselves for examination before the end of their third winter, that is to say, they may be ready in all respects by the end of the second summer but must wait another nine months before they can be examined in the subject. This is unfair on the student and it operates detrimentally upon his work For human nature being what it is it is improbable that a man will devote himself with the same earnestness to the study of a subject which he will not be examined upon for nearly two years as he would were the examination to come at the end of the courses he is attending It is a distinct hardship that students who may have completed their courses either in anatomy or in physiology by the end of the second annus medicus are prevented from presenting themselves for examination in either of these subjects for nearly a year I put this before you as one of the examples which should *not* be followed in framing the curriculum for your university

An important principle to be kept in mind in settling the periods of examination is so to arrange matters that there shall be no year, and if possible no term of study without its corresponding examination or examinations For, as has just been pointed out, do what you will to urge the necessity of work, many students will not work except with a view to the immediate exigencies of an examination If the examinations for each subject are to be taken separately they would necessarily come even more often than at the end of each annus medicus And if subjects require a second year of study—as with practical anatomy—there should always be an examination at the end of the first year or at the end of the first winter This may be elementary or it may embrace a part only of the subject, but it will serve to stimulate work during that year and render the student better able to attack the work of the second year To take again the example with which I am most familiar, that of Edinburgh The student there during his second year is studying anatomy and physiology, which he cannot be examined in before the end of his third winter, and surgery, for which the examination comes at the end of the fifth year The result is *that a number of students, who have not at that* early stage in the curriculum yet acquired a full sense of responsibility, yield to the tendency to procrastination which is inherent in most of us and devote a large part of their energy during the second annus medicus to the recuperation of their physical forces The result is excellent so far as university athletics is concerned but is much less successful from the academic standpoint I would strongly urge in *the real interest of the student whose future career does* not depend upon his proficiency as an athlete that this should not be possible In saying this I would not be understood to imply any discouragement of athletics which in my judgment should play an important part in the amenities of every university But they are not the most important element and should never be allowed to interfere with the main purpose of a student s career By all means encourage *all those manly games the pursuit of which has given a* characteristically healthy tone to university life in this country, but let this pursuit take its proper place in the curriculum and do not let it at any stage override the pursuit of knowledge

In conclusion I will in a few words sketch out what I should regard as in existing circumstances, the best manner in which the subjects of the medical curriculum can be arranged *Supposing that a student enters in October*, as most do In his first winter he would study only chemistry and physics and would present himself for examination in those subjects at the end of the winter In his first summer he would take a course of biology including the lower forms of plant life but mainly founded on comparative anatomy A course of botany strictly so called is, in my judgment, not essential to a scheme of medical education *The examination in biology would* immediately follow The second winter would be occupied by courses of lectures on anatomy and physiology, by courses of practical physiology, and by attendance in the dissecting room, the second summer by attendance on practical histology, with such expository lectures as might be considered necessary, and by a continuance of dissection At the end of this summer the student should be allowed to present himself for examination in physiology if he is sufficiently prepared. A certain number will be able to do so, while others may need to defer the subject for six months; if this is done an advanced course may be taken in the following winter The third winter will be occupied by dissections and anatomical demonstrations and by lectures and practical instruction in pharmacology which would follow naturally upon the courses of physiology Those students who have completed their dissection of the body by the end of the first winter term—i e, by Christmas—might be permitted to present themselves then for examination in anatomy—otherwise they would defer the examination until the end of the second term (Easter) The examination in pharmacology would naturally come at the end of the third winter

After anatomy and physiology are finished clinical work may be allowed to begin with the holding of a clerkship in one of the medical wards to be followed by a dressership in the surgical wards *Such appointments should always be continued during the vacations* During the third summer a course of pathological anatomy and histology—lectures and practical—would be taken as well as a course of bacteriology and this would also be a suitable time for including the subject of public health—examinations in these subjects coming at the end of that summer The fourth winter would be occupied by medicine and therapeutics and by general pathology, including practical work in experimental and chemical pathology, the interest in these subjects would be enhanced by the previous attendance in the medical wards and in the post-mortem room The examination in pathology would come at the end of the fourth winter and certain parts of medicine might now also be taken The fourth summer session would be occupied by attendance on midwifery and on a separate three months' course of instruction in the special diseases of women and children to be followed as before by examination in those subjects Practical midwifery would be attended at any time after the systematic instruction had been taken

The fifth winter would be devoted to attendance on systematic surgery surgical anatomy, operative surgery, ophthalmic medicine and surgery and diseases of the ear, nose and throat. The use of anæsthetics and instruction in vaccination might also be conveniently taken at this period The course of systematic surgery would extend over six months but the other courses would each occupy not more than half that time At the end of this fifth winter would come the examination in surgery The April vacation and summer of this fifth year would be devoted to attendance at a fever hospital and an asylum to lectures on mental diseases and on forensic medicine and at the end would come the examinations in forensic medicine and the final examination in medicine The curriculum as here planned out can readily be modified to meet the case of instruction in surgery being taken before instruction in medicine, if this—the more usual course—were preferred In that event a dressership would precede a clerkship the fourth winter would be devoted to the surgical subjects and to pathology and the whole of the fifth year to medical subjects the examination in surgery being taken at the end of the fourth winter and all the examinations in medicine at the end of the fifth year

The student is now equipped with his degree of M B, B S, and thereby receives his qualification to practise In some universities he passes after a certain period of time to take up his M D or M S without further examination or other test of work or knowledge In the University of London before its reorganisation a severe examination was demanded before either of these titles was conferred In the Scottish universities and in the universities of Germany and most foreign universities it has long been the custom to demand the presentation of a thesis upon some subject in medicine or surgery or in one of the related sciences This is a custom you will do well to follow in this university, for it has the undeniable advantage of promoting research and has in the past been productive of a large amount of original work which although it may sometimes have been mediocre has in many cases proved of a high order of merit As an alternative to the presentation of a thesis the candidate may be allowed to present himself for examination, such examination being either in general medicine or surgery or in some special branch which the candidate may himself select such as midwifery, gynæcology, ophthalmic surgery, or public health. In this way encouragement is afforded to specialisation after a general knowledge of medicine and surgery has been acquired. In some of the best American universities specialisation is encouraged even for the work of the pass degree. We are also, of course, familiar in this country with the specialisation which is necessary for the diploma of a dental surgeon. But for those who are to receive a diploma to practise medicine and surgery a thorough groundwork in all branches of these subjects seems requisite, even if they intend to practise in only a limited branch. The time of the ordinary curriculum is fully occupied in furnishing this groundwork; nor do I think that any of the subjects I have enumerated could well be omitted from a general course of medical education which is to confer the diploma to practise.

I will not apologise for having taken up time with these details, for it is only by the plotting out of details that the working of general principles can be illustrated. These principles, however, must not be lost sight of in considering the arrangement of the details and I will therefore again state them in the briefest possible terms: (1) the relegation of some or all of the preliminary scientific subjects to the year or two preceding entry in the medical school: the examination in these subjects should be not only permitted but encouraged before entry; (2) the maintenance of a proper sequence of subjects so that in no case should any subject be begun until those on which it is founded have been mastered; and (3) the breaking up of the examinations and the taking of the examination in each subject as far as possible immediately after the courses of instruction in that subject are completed. I am confident that the carrying out of these principles will greatly lighten the curriculum which in its present form is a grievous burden on the student and that so far from having a tendency to lower the standard of knowledge it will help to raise this standard although rendering the degree more easy to obtain. It is, as you will see, no unattainable ideal which I have set before you but a plan of study and examination which is easily capable of realisation. The medical school in Leeds is for its size one of the best appointed and the hospital with which it is connected is one of the noblest in the kingdom. The opportunity which presents itself of carrying out such a plan may never recur. "There is a tide in the affairs of" institutions as of "men which taken at the flood leads on to fortune" but if left to ebb will leave them stranded in obscurity. Let it be yours to steer the good ship which is intrusted to you free of the shoals of obsolete tradition into the clear channels which have been buoyed by science, along which the tide of progress is now swiftly flowing.

CHARING CROSS HOSPITAL.

OPENING ADDRESS BY SIR CHARLES WYNDHAM.

AFTER a few introductory remarks in which he referred with real humour to the steps which had led him to take upon himself the office of giving an address Sir Charles Wyndham said:—

You will naturally expect me first to congratulate the prize-winners. Pardon me if I do the very opposite—advisedly. For what is the position of these brilliant young gentlemen who have been proclaimed victors in these contests? One I would not accept for worlds. They have given hostages to fortune. They are doomed through life to live up to their present eminence and woe betide them if they are lulled into indolence or tempted to rest on these early laurels. No They are certainly entitled to our appreciation, but our felicitations are due to those who have contended manfully in this intellectual arena, though for the moment without tangible result. No Capua invites them to inglorious repose. Theirs is the tonic of unsatisfied ambition, not the possible opiate of gorged achievement.

> "Act well your part; therein the honour lies.
> The virtue's in the struggle, not the prize."

Seriously, I tender my congratulations to all of you who have worked well, whether prizes have or have not fallen to your lot. Work is the one thing worthy of honour. It is the one thing that wins the most solid treasure that life has to give—that supreme consciousness of having put forth the best the worker has in him. The divinest artist demands no more than this; the humblest servant maid achieves no less:—

> "Who sweeps a room as for Thy laws
> Makes that and the action fine."

And now in approaching the most difficult part of my undertaking I pause to wonder in what capacity I shall do so. Shall it be in no special character at all beyond that of the mere layman? If so, what advice can a medical student usefully receive from a layman? The only precedent at my disposal is when the medical student consulted Mephistopheles and the suggestions made by that sulphurous layman were characterised by such deplorable immorality that I dare not take him as my example. It is, on the contrary, my humble ambition to make my observations at least respectable if even pre-eminently dull. Or shall I address you as one who formerly had the honour to belong to the profession you are about to enter? I am entitled to do so. My diplomas are in order, therefore I stand before you legally supposed neither quite unlessoned nor unpractised. Indeed, it is competent upon me to operate upon or to prescribe for any one of you who may have the pluck to entrust himself to my tender mercies. Do not all speak at once. But, alas, "a little learning is a dangerous thing," the lessons of those early days have long since been forgotten, and the theatres in which *my* operations are now conducted are not of a surgical character. Theoretically I may belong to you, practically I stand apart. Apart, but not aloof. For the memory of that part in my life which is now the present and will be the future in yours is to me a bond between us that the rapid and ruthless passage of years can never wholly deface. Or shall I deliver myself of my rambling observations in the character of a mere man of the world, with such value as the difference in our ages may attach to them? A man who like myself has, well, escaped from his first youth must presumably have gathered something from his experience which he can impart to others. In short, I am not too young to give you, nor you too old to receive, a few discursive general hints. Gentlemen, my first counsel to you may seem commonplace: most good advice is. I would urge you to put before and above everything else the primary virtue of loyalty to your profession. I do not mean mere sticking to one another. Valuable as this quality is it may mean or may degenerate into nothing better than trade unionism or the slavish bondage of etiquette to the prejudice of weightier matters. I mean loyalty to the great ideals of the profession. You cannot put them too high. You cannot have too exalted a conception of the vast importance, the nobility, I would almost say the sanctity, of your vocation. There is none to surpass it in the purity and unselfishness of its aims, the multitude of points at which it touches life or the intimacy of its relations to the community, the household, and the individual. "Man," said Bacon, "is the minister and interpreter of nature." The medical art is the minister and interpreter of man. Your influence over the lives, thoughts, pursuits, and desires thus laid bare before you will be enormous. You will be conversant with the simple annals of the poor and the inner lives of the great. You will be welcomed as a friend in the cottage and you may stand on the steps of a throne, blessed by the lowly, desired, even sometimes feared, by the mighty. More to Louis XI. than all the remonstrances of his counsellors, the denunciation of his confessor, the relics of the saints, or the leaden images of the Virgin above his brow, was the uplifted finger of his physician. And the interaction of body and mind is such that no one can treat the one without treating the other too. There have been some extremists who have held that all bodily states are pure creations of the mind; others that all mental states are merely products of the physical organism; or, as Condorcet tersely puts it, "Virtue is a gas and poetry a secretion." Each of these extreme theories has long since been discarded and it is now recognised that by processes mysterious in origin but discernible in action mind and body determinate and mould one another, whilst the empire of medicine dominates both for the preservation of the lives and happiness of its subjects. In exact proportion therefore to the vastness and stringency of this empire are the responsibility of its administrators and the need for those essential qualities of watchfulness, tact, sympathy, and discretion. But do not let this seduce you into even the faintest suspicion of misusing the dominion which you will necessarily possess over the lives and interests of those committed to your charge—whose habits, modes of thought, and human weaknesses will be an open book to you. It is because this danger is so insidious that the law in its wisdom has placed the relation of medical man and patient in the same category as those existing between the priest and penitent, the solicitor and client, not because medical men, solicitors, and priests are dishonourable men or undeserving of grateful recognition, but because the mere existence and intimacy of the relation raise of themselves the presumption of supremacy on the one side and subjection on the other. Do not forget either that you are frequently the repository of private and family confidences, often withheld from the friend or the priest, the husband or the wife, the son or the father, needing on your part the utmost delicacy and discretion. It is sometimes dangerous even to whisper to your nearest and dearest the secrets of the sick room. On the other hand, do not cultivate reticence at the expense of other and equally important qualities. Science demands courage also from its votaries. I do not mean physical courage. It is quite unnecessary to speak of physical courage when addressing a body of young Englishmen entering a profession whose annals blaze with the records of heroism on land and sea, at home and abroad, on the field of battle, in the hospital, the wilderness, and the slum. I mean moral courage. In this age when the smaller vices are multiplying, each with its attendant nemesis of disease, have the courage to call things by their proper names. If a patient courts death or misery by drink, drugs, or vicious life tell him so in the plainest terms. Do not disguise the truth by some euphemistic Greek words ending in "itis"—words which fall weakly on one coward's ears and issue lightly from another coward's lips. To gloss over the vice which causes—nay, is—the disease and thereby to encourage its continuance is high treason to your profession. There are occasions when silence is not golden—cases to which an agreeable bedside manner is less appropriate than a dash of the caustic, sturdy honesty of an Abernethy. These moral requisites of your calling are summed up in the embracing virtue of loyalty—to your profession, to your patients, and to yourselves. No less exacting, however, are the demands made by your vocation upon the intellectual side of your nature. Never was there a time in the history of the healing art when greater alertness and versatility of mind were required by its practitioners to cope with the ever-increasing rapidity of development. Life as it is to-day, when we contrast it even with what it was in the early part of the Victorian era, has become a thousand fold more complex and it will tax all your energies to keep abreast of this growing complexity. New pursuits, new habits, new vices and their consequences, and new diseases, on the one hand, have provoked new theories, new methods, and new remedies on the other. Each successive invention, whether for utility or amusement—railways, lawn tennis, cycles, motor cars, even the fascinating game of bridge, if too fascinating, the growing recourse to opium, chloral, morphia, cocaine, ether, and other deadly poisons—each has carried with it its special ailment and demands its special treatment. Increasing variety of disease demands at your hands increasing resourcefulness. And it will be your own fault if with such armouries and stores as are ready to your hand you are caught by the enemy tripping. At the same time, everything will depend upon yourselves. Material resources will be nothing without the individual brain, lectures and books mere baggage unless properly applied, whilst there is one book of which not this or any other institution has the copyright—the vast volume of human life which lies open to the exploration of any of you. And it is worth every effort on your part. You will have the sympathy and appreciation of everyone to help you. Never has your profession stood higher in man's estimation than now. You have, on the one hand, the most practical Sovereign of the day, our King, faithfully interpreting to you the sentiment of his subjects and, on the other hand, the voice of the nation to sustain you. The large space you occupy in men's minds and hearts is as you see reflected in modern literature and art. The physician has outlived the satire of Molière. To-day the painter, the novelist and the dramatist vie with each other in doing homage to his character. Remember the sensation caused by the picture which a few years ago adorned the walls of the Academy—the doctor fighting for his patient's life through the long watches of the night and inch by inch disputing the ground with death. As on canvas so in print, and upon the stage the physician and the surgeon are proclaimed the friends of men to be loved for the good they do, not, as used to be, the enemies to be feared for the evil they may do. But do not forget that though you start with the goodwill of men and with vast scientific achievements and discoveries at your back there are still many unsolved problems to stir your ardour. Alexander's lament need not be yours, there are still many worlds for you to conquer. Though you wend your steep triumphal way to the Capitol with many a captive bacillus at your chariot wheel there are many more which still elude your vigilance and do not own your sway. Which of you, I wonder, is destined to win imperishable fame as the discoverer of the definite cure for our national scourge, consumption? Whence will come the living radium to burn out that fell destroyer cancer? Gentlemen, it may not be given to all of you to establish epoch making discoveries or to write great books or to become fashionable physicians. Harley-street is not long enough to accommodate every one of you, but it is open to all of you to descend into the arena and to contribute your quota to the ceaseless conflict. For many as are the mysteries which the healing art has fathomed of late, they are as nothing beside that vast, bitter, unplumbed ocean of human disease which still ceaselessly throbs and tosses on the rocky bed of pain and moans around you with its many voices.

KING'S COLLEGE HOSPITAL

INTRODUCTORY ADDRESS ON THE BIOLOGY OF IMPERIAL FEDERATION BY SIR JOHN ALEXANDER COCKBURN, K.C.M.G., M.D. LOND. & ADEL.

THE evolution of the empire is a subject of engrossing solicitude to all British subjects and is of especial interest to a great centre of higher education such as King's College. The world wide possessions of Great Britain present an unparalleled field of activity for every well equipped medical student and science itself owes much to the facilities for travel and research afforded by so vast and varied an area. Who shall say what every department of knowledge would have missed if Charles Darwin had been born in an inland country like Switzerland and had not enjoyed the opportunities for investigation into all forms of life in every climate which were thrown in his way in the navy of the greatest sea power? We live in an age of consolidation. Cables and steam have so contracted the earth's surface that the nation, as the unit of power, no longer suffices. All now aim at empire. The rivalry of the future will be, not between nations, but between empires of which nations are the component parts.

Casting a glance over the page of history we witness the steady advance of the Anglo Saxon race in this direction. The heptarchy a thousand years ago was fused, under the first Edward, into the Crown of England. After centuries of struggle the United Kingdom was evolved, but this goal proved to be only the commencement of a still wider course. The Union Jack, the emblem of that consummation, is but the parent of a family of flags which mark the extended sway of King Edward VII who, true to the traditions of his name, was the first to incorporate in his Royal title "the Britains beyond the Seas." One striking feature of this stupendous imperial growth is that it has been, for the most part, unconscious and has taken place against the will of those who were supposed to be its directing intelligence. As Professor Seeley wrote, "We seem, as it were, to have conquered and peopled half the world in a fit of absence of mind." To the physiologist this unconscious working out of destiny is no strange matter. He knows well that nature is ever chary of intrusting vital operations to human intelligence. Even in our own bodies she is careful to place the control of the organs on which the maintenance of our existence depends beyond the reach of our volition and it is not to be expected she should be less solicitous of the welfare of the race than of the individual for "so careful of the type she seems so careless of the single life." Signs are not wanting, however, that the long period of unconscious incubation is now passed. The imperial idea is surging into a corporate consciousness. Henceforth our intelligence must reinforce and elaborate the instinctive operation.

All authorities are now agreed that there is a close analogy, if not identity, between the laws which govern the evolution of living beings and societies. Some even affirm that a preliminary study of biology is necessary for the comprehension of sociology. Undoubtedly, by such a course many phenomena which appear paradoxical to the ordinary observer would be readily explained. The history of Australian federation furnishes an example of such a paradox. The advocacy of some form of union originated even before the process of fission of Queensland and Victoria from the mother colony of New South Wales had taken place. The simultaneous working of these apparently contrary forces of separation and union however, is no puzzle to the biologist. For him the veil of nature's mysteries is raised. The laws of life, so full of enigmas to others, are but as his hornbook and primer. To him differentiation and integration appear as the complementary manifestation of the same evolutionary force and he recognises that the union resulting from the coöperation of the differentiated colonies was on a far higher plan of organisation than if previous segmentation had not taken place. Similarly when in the latter half of the nineteenth century statesmen set themselves deliberately to bring about the separation of the colonies it seemed as if the knell of the colonial empire had been tolled, whereas studied apathy and neglect at headquarters proved to be but the necessary conditions to develop strong, self-reliant, mobile, and firmly attached members of the empire. It was merely a step in the devolution and decentralisation necessary to produce the variation of a highly developed organism.

The dictum of Turgot that colonies are like fruits which cling to the tree only till they ripen does not hold except in the case of simple social organisms. The Greeks, whose form of government was limited to a single city, knew no other method of colonisation than by complete separation. The parallel to this is to be found in the unicellular protozoon. In higher and more complex structures subdivision is not attended with separation; the cells, although differentiated, remain attached to one another and perform various but coördinated functions. And here, doubtless, we find the parallel to the colonial empire of Great Britain. The concession of complete powers of self-government and local freedom have created sturdy individualities which are ready to be brought into coöperation and collective strength by the integrating force now so strongly manifested. With regard to this consolidating process all undue haste should be avoided; our motto should be "*Festina lente.*" In pathological processes which go from bad to worse it is often necessary to bear in mind the maxim, "When in doubt operate," but in physiological processes where nature usually guarantees the result the opposite is the rule; for example, it is well known that meddlesome midwifery is bad. Imperial federation must be a growth, not a manufacture. "From lower to the higher next not to the top is nature's text." At the same time we must bear in mind that nature herself runs rapidly through stages of evolution which previous experiences have rendered familiar. Australian ederation was a gradual growth although eventually the onstitution was framed in the space of a few months. It was in reality the result of ages of evolution from the Achæan and other ancient leagues through the modern nstances of the United States, Switzerland, Canada, and Germany, just as the embryo presents an epitome of the history of the race, and passes through in a few days stages which thousands of ages in the first instance were required o accomplish.

At one time in our lives we all had tails and gill clefts n our necks, but we did not remain long in that condition. In ascending to imperial federation if we heedfully follow in steps already trodden our progress may be comparatively swift and sure. We know that our union must be on the federal plan; no other is so flexible and firm or so suitable for maintaining a vast territory under that local self government which constitutes the genius of our race and from which is derived our colonising power. Eventually there will be a Pan Britannic Federal Constitution with an Imperial Parliament consisting of a Senate representing the component nations and an assembly with representatives in proportion to the population of each, together with untrammelled trade throughout the whole. But this goal is far distant and none of us may live to see the day. Meanwhile we must so traverse the intervening territory that each step may bring us nearer to it. The colonial conferences of 1887, 1897, and 1902 did much to prepare the way. In future these are to be periodical. Mr. Chamberlain, strong yet ever cautious, prevented many difficulties by consulting the colonies in all questions affecting their interests. An advisory council consisting of representatives in London of the self-governing colonies might with advantage be formed as a stepping-stone to an imperial council. The desire for closer union was never so strong as at present and advantage should be taken of it to extend in every direction mutual interest; this is the soil in which sentiment permanently flourishes, otherwise it is an exotic which a frost may kill. The strange heresy which prevents natural affection from manifesting itself in the channels of trade is rapidly dying out and the way will soon be open for such reciprocity as will eventually lead to intra-Imperial free trade. Common prudence dictates that adequate steps should be taken to secure our supply of daily bread. At present Great Britain depends for nourishment on foreign sources which must be seriously affected or interrupted by a European war or possibly even by market operations. We are in the position of a patient whose supply of nutrient fluid is insufficient for his needs and requires to be sustained by a continuous transfusion of blood from other individuals. In an age of progress every social organism must either advance to a higher stage of organisation or must retrogress. It is true we stand at the parting of the ways but there can be no doubt as to the course that will be pursued. It cannot be that the empire in the recent thrill of realisation attained self-consciousness only to witness its own decay. The divinity which has shaped our ends through so many ages can safely be trusted to guide our steps to the higher life of relationship which has ever been clearly our destiny.

THE MIDDLESEX HOSPITAL.

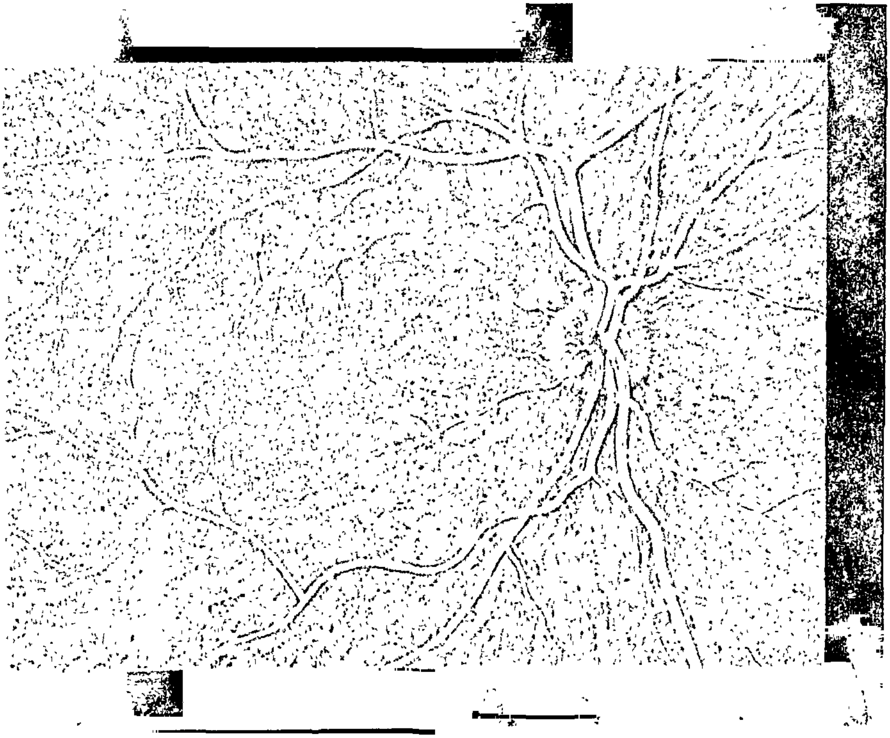
INTRODUCTORY ADDRESS BY WILLIAM HERN, M.R.C.S. ENG., L.D.S.

IN welcoming the new students to the Middlesex Hospital Mr. William Hern dwelt on the value of medicine as a calling in that it developed the highest faculties of man and afforded the widest scope for the exercise of courage, perseverance, tact, and human kindness. He referred also to the enhanced facilities now offered by the well-equipped laboratories and class-rooms lately opened at the Middlesex Hospital Medical School for the acquisition of scientific professional knowledge.

One of the great differences between the medical methods of past and present times, Mr. Hern proceeded to point out, was the substitution for the old empiricism of treatment based upon an inquiry into the causes of disease. The modern practitioner must resemble the farmer who knew and betimes destroyed the sources of blight and mildew. From the utilitarian point of view the labours of the patient investigator into the causes of disease far outweighed in value the devotion and self-sacrifice of the unscientific philanthropist and guardian of the sick. The popular tendency was to ignore the causes of ill-health. Had the physician in *Macbeth* complied with the king's request to find the disease of the commonwealth he must have pointed to the unsuspecting king himself. Martyrs to the results of evil habits and the thralls of dental disease seemed to regard their troubles as the thorns that must inevitably spring into being with the rose of life. Their satisfaction in the possession of remedies for a complaint must not blind them to the necessity of doing all they could to render that complaint impossible. To this end the medical man required to impress upon the people the strict observance in everyday life of hygienic principles. Thus alone might the visits of the medical man be rendered few and far between. A sick man's recital of his woes had usually reference to his symptoms only; the medical man's duty was to discover and to treat the underlying cause.

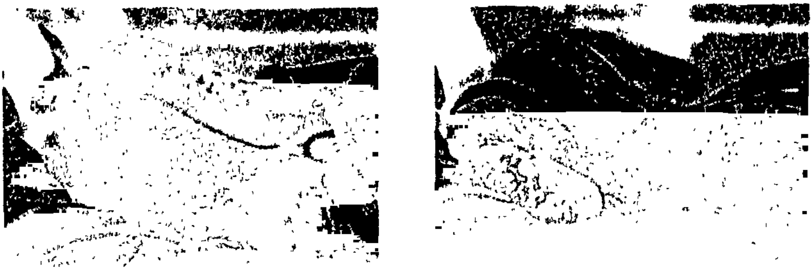
Oral sepsis—i.e., a foul and infectious condition of the mouth cavity—and dental caries or decay were affections of which it was most important to ascertain the origin. The mouth, being open to the air, moist, and warm, and having distributed in it from time to time the débris of food (itself the habitat of minute organisms) served as a most efficient catchment chamber and breeding house for rapidly multiplying disease germs. Following in the steps of Leuwenhoek, a seventeenth century investigator, Galippe, Miller, and others had been able to demonstrate that though some of the micro-organisms of the mouth were harmless to man, others might occur therein which had been identified as associated with maladies the most deadly to human kind. The effect of the mischief-working germs on the gums was to produce inflammation therein which might lead to loss of teeth through suppurative inflammation, to general but minor disturbances of health, or to acute and fatal blood poisoning. That the worst possible results did not commonly follow on prolonged oral sepsis was due probably to the fact that the patient by degrees became to some extent immune to his own poison.

Dental caries, or decay of the teeth, was a disease of all ages of the world's history and most rife among civilised peoples. Nearly 80 per cent. of the children in industrial schools were found in an investigation by the British



TO ILLUSTRATE DR. HALE WHITE'S CASE OF DIABETIC INTRAOCULAR LIPÆMIA.

PHOTOGRAPHS, IN NATURAL COLOURS, OF A CASE OF PURPURIC ERUPTION.



Dental Association not long ago to be subjects of it. Of some half-dozen theories which had been advanced to account for dental caries that which might be termed the "chemico-parasitic," attributing the affection to the work of disease germs, was the one now regarded as tenable. The predisposing causes of caries—those which might be said to prepare the soil for the parasitic growths—included abnormalities in the form, structure, and position of the teeth, debilitating illnesses, congenital tendencies, certain occupations, the somewhat obscure influences which came under the head of "civilisation," and last, and mainly, the diet, more especially one consisting largely of vegetable matter and, he might add, milk. But that which constituted the primary, or exciting, causes of caries was the *form* and situation of the various parts of the teeth, whether such as would retain decomposing and therefore infectious food débris or such as being rounded or continually swept by the tongue and lips did not admit of the lodgment of particles. It followed from this that though the teeth of a robust man did not suffer in the same degree they showed caries in the same positions as in the teeth of the sickliest and most weakly of mortals.

Experiments with sound natural teeth placed in various mixtures had evolved the following facts. Albuminous and fatty matters mixed with saliva and kept warm produced by decomposition an alkaline liquid, non-causative of caries. Starchy and saccharine food similarly treated yielded an acid solution which, like a weak solution of lactic acid, decalcified the teeth and effected the first stage of caries; the second stage was accomplished by the solvent action of micro-organisms provided by the saliva. For the prevention of caries, therefore, the important desiderata were, first and foremost, regular and systematic sweeping of the teeth with tooth brushes stiff enough thoroughly to clear away remnants of food; and, secondly, the use of antiseptic mouth washes. That these measures and the consequence of their neglect had not been brought before the lower orders of society, their children especially, was a reproach to preventive medicine, if not to the State. Thousands of patients yearly attended the hospitals because of ailments directly or indirectly due to unclean mouths, caries, or loss of teeth. A State which could afford to control the drunkard, to provide the poor with free education, and to appoint ophthalmic surgeons to board schools should surely be able to organise some system of gratuitous dental supervision and treatment to supplement the necessarily limited work of the few existing dental hospitals. If it should be impossible to institute State aided dental dispensaries there might at least be provision for instructing the children of the poor in oral hygiene. The cause no less than the effects of oral sepsis or caries must be constantly within the purview of the [illegible] and it is only by the coopera[illegible] healing art in inculcating pre[illegible] be successfully combated.

Knowledge of the importance of good teeth to the well-being of the body and instruction how best to preserve them should be imparted to all patients, especially the poor and ignorant, and the nurse who attended to the ablution of the body should see even more punctiliously to the cleansing of the teeth. Acquaintance with dental pathology afforded valuable clues to the physician, the surgeon, and the throat, the ear, and the eye specialist in tracing the origin of maladies of the most diverse kinds, and he who by timely warning and advice sought to save his patients from the evil consequences of oral sepsis and dental caries was choosing the better part of medicine—the prevention of disease, which was better than the most brilliant cure.

A NEW HYGROMETER.—The *Engineer* of Oct. 2nd states that an Italian has invented a saturation hygrometer which may be used for determining the tension of aqueous vapour in the air in small spaces, such as instrument cases; a portion of the air to be examined is withdrawn and saturated with aqueous vapour, and the increase of pressure thus caused is noted; knowing the saturation vapour pressure it is possible to deduce the aqueous vapour pressure of the experimental air. The apparatus consists of a bronze receiver fitted with a thermometer; into the receiver passes a glass tube drawn out at the lower end and connected at the upper end with a syringe which serves to force in drops of water. The receiver may be put in communication with the exterior [illegible] a graduated tube of 3·2 millimetres

---

A CASE OF

DIABETIC INTRAOCULAR LIPÆMIA, IN WHICH THE BLOOD WAS EXAMINED DURING LIFE.

BY W. HALE WHITE, M.D., F.R.C.P. LOND.,
PHYSICIAN TO, AND LECTURER ON MEDICINE AT, GUY'S HOSPITAL;
EXAMINER IN MEDICINE AT THE UNIVERSITY OF CAMBRIDGE.

(*With Coloured Illustration.*)

IN 1880 Heyl[1] published an account of a case of lipæmia in diabetes, in which the fatty blood was recognised in the retinal vessels by means of the ophthalmoscope. The title of his paper is "Intraocular Lipæmia." Although it is so long since this observation was made yet text-books do not allude to the appearance and even Naunyn[2] does not mention it, hence it seemed to me worth while to record the following case. Owing to the time occupied in preparing the accompanying chromolithograph the publication of this case has not been possible till now, but in a clinical lecture published in 1902[3] I mentioned I had seen intraocular lipæmia, and again when opening the debate on diabetes at the Chelsea Clinical Society in March, 1903.[4] Recently Sir T. R. Fraser[5] recorded a case at the Edinburgh Medico-Chirurgical Society, and in the *Ophthalmoscope*[6] there is an abstract of a case published in Germany by Reis. For this reference[7] I am indebted to Mr. A. W. Ormond. I should not, for my own part, say that lipæmia in diabetes is excessively rare and I know of at least one other patient in Guy's Hospital in whom this condition of the blood was observed in the retinal vessels. I have called the condition "lipæmia," for this word is constantly used in describing the blood when it is of a pale salmon colour. This is most often seen in diabetes, but it has also been described as occurring in alcoholism, phosphorus poisoning, pneumonia, peritonitis, and gout. Of these rarer causes probably alcoholism is the most frequent. Most authors say that under the microscope fat globules may be seen and also very fine granules. In many cases undoubted fat granules are present for they are described as staining with osmic acid and they are so depicted by Saunders and Hamilton.[8] But these authors, like others, also describe "a finely granular precipitate evidently not of an oily nature," and they also speak of the albuminoid precipitate as showing no change with osmic acid. Futchner[9] found that the turbidity of the blood was only in part cleared with ether and many of the granules were not stained black by osmic acid, and he points out that the turbidity is only partially due to fat and suggests that the granules are in part albuminous. Others have suggested that the granules are particles of fat surrounded by an albuminous envelope.

One of the points of interest in the case about to be recorded is that a careful microscopic examination of the blood failed to show any fat globules or anything that stained with osmic acid, and so we learn that this pale, turbid, salmon-coloured blood may contain not only fat globules and a [illegible] insoluble in water and salines, but more or less soluble in alkalies. It seems to be a proteid precipitated out by the presence of a fatty substance, but what the proteid is I was not able to discover. The fatty substance is not true fat but apparently an ester of cholesterine with one of the higher fatty acids, or a mixture of them. I extracted the ester from the precipitated body with alcohol and saponified with alcoholic soda and then extracted the residue with hot chloroform. This on evaporation leaves cholesterine, which gives the usual tests and was also identified by its crystalline form. I could not possibly tell, of course, the acid with which it was originally combined." We thus learn that the term "lipæmia" is not strictly correct, for the turbidity is not entirely due to fat globules—indeed, they may be absent when the turbidity is marked and that then, in addition to a precipitated proteid, there is present a substance which, although allied to fats, is not a true fat.

---

[1] Transactions of the American Ophthalmological Society, 1880, p. 54.

[2] Der Diabetes Mellitus, Nothnagel's Specielle Pathologie und Therapie, Band vii., Theil 6.

The ophthalmoscopic appearances in my case can be seen in the appended chromolithograph, kindly made by Mr. Arthur W. Head. The arteries and veins, it will be noticed, contain blood of a similar colour, and this colour is a deep cream which in the larger vessels passes into a pale salmon colour, for here there are enough blood corpuscles visibly to modify the cream colour. The vessels appear a little larger than usual; the whole retina is pale. Reference to Heyl's paper will show that this description, which was written before I read his, accords with it. Unfortunately, when the patient was under observation I was unaware of Heyl's paper and consequently of the interesting discussion raised in it as to why the vessels appear large.

Most cases of diabetic lipæmia that have been recorded have been fatal and it has been suggested that the lipæmia is the cause of the coma. That is not now believed and I can testify that it is not so, for I have in many fatal cases of coma failed to find this condition of blood. My case, like Fatchner's, shows that as the patient improves the lipæmia disappears; further, it shows that as the lipæmia goes the fundus of the eye becomes healthy-looking. No satisfactory explanation of the lipæmia has been given. Certainly in my case it bore no relation to diet.

The patient, a man, aged 26 years, was admitted under my care into Philip ward, Guy's Hospital, on Feb. 13th, 1902, on account of hunger, thirst, polyuria, weakness, and wasting. The weakness was noticed first about nine months previously. In September, 1901, the thirst appeared and since Oct. 21st of the same year, when he first came to the hospital, he had been treated for diabetes as an out-patient. For a time he did well and gained weight, but latterly he had not kept at all to the diet ordered and he had become drowsy. On admission he was drowsy and felt sleepy. His body was wasted. His breath smelt very sweet and he had a sweet taste in his mouth. He complained of pain in the loins. His tongue was red. The sugar in the urine was 2595 grains in the 24 hours. The total quantity was 178 fluid ounces, the specific gravity being 1040. One part per 1000 of albumin and 770 grains of urea were present. There was a well-marked ferric chloride reaction. Under treatment the sugar finally fell before he went out on May 26th, 1902, to between 1000 and 1500 grains in the 24 hours, the total quantity becoming about 80 fluid ounces. The specific gravity was between 1030 and 1035 and the total daily excretion of urea was between 600 and 900 grains. The ferric chloride reaction was well given during the whole of his stay; the albumin gradually disappeared. Mr. E. H. B. Milsom, the clinical clerk in charge of the case, even after the patient had been in some time, prepared large quantities of crotonic acid from the urine. He found the total ammonia in the urine on March 10th to be 2 565 grammes, both these facts pointing to the presence of a large amount of oxybutyric acid. The patient was treated by restricted diet and after he had been on this for ten days he was allowed two ounces of lævulose a day. He liked this very much. It did not lead to any increase of the sugar in the urine, nor did it appear to make him worse in any way. The transition from ordinary to diabetic diet was made gradually. He was throughout allowed milk and as he was so drowsy on admission he was given three pints of milk a day and to each pint 100 grains of bicarbonate of soda were added. Before this was done he was so drowsy that a fatal issue seemed probable and it was difficult not to believe that the administration of the bicarbonate of soda diminished the drowsiness, for it gradually became less and ultimately quite passed away. He was allowed milk because, as he was semicomatose, it seemed undesirable that he should have an entirely carbohydrate-free diet.

The main interest of the case lies in the blood. On admission, directly we looked at his eyes we noticed that the retinal arteries and veins both appeared to have in them blood of a pale salmon colour. The retina was pale. As the patient improved the colour in both sets of vessels became more healthy and was quite natural after he had been in for two months. He was fortunately an intelligent man and on Feb. 19th he allowed us to bleed him, only a small quantity of blood being taken. It was very milky and the serum after clotting was milky. Under the micropscope many fine granules were seen, but no globules or anything that stained with osmic acid. On March 17th he was again venesected and the blood was sent to Mr. Cole, whose report has been given. The patient's improvement is shown by the following weights: Feb. 26th, 105 pounds; March 2nd, 114 pounds; March 18th, 115 pounds; March 23rd, 118 pounds; March 27th, 120 pounds; April 5th, 123 pounds; April 26th, 126 pounds; May 3rd, 128 pounds. I should add that Mr. A. W. Ormond, the ophthalmic registrar to Guy's Hospital, kindly introduced the case to Mr. Head's notice and hence we are indebted to him for the chromolithograph, and I am also much indebted to Mr. Milsom for his many careful analyses of the urine.

Harley-street, W.

ON THE PROTECTIVE EFFECT ACHIEVED BY ANTITYPHOID INOCULATION AS EXHIBITED IN TWO FURTHER STATISTICAL RECORDS.

BY A. E. WRIGHT, M.D. DUB.,
LATE PROFESSOR OF PATHOLOGY, ARMY MEDICAL SCHOOL, NETLEY; PATHOLOGIST TO ST. MARY'S HOSPITAL, PADDINGTON, W.

IN the issue of THE LANCET of Sept. 6th, 1902 (p. 651), I gathered together and set forth in a synoptical table all the statistical materials which were available up to that date. In a special supplement appended to the same issue I marshalled the materials for the critical estimation of the value of each of the statistics. I have recently been permitted to publish, through the kindness of Surgeon-General Sir William Taylor, K C.B., Director-General of the Army Medical Service, two further statistical records received at the War Office since the date of the publication above referred to.

The first refers to the incidence of typhoid fever and the death-rate from the disease in inoculated and uninoculated soldiers in India during the year 1901 (vide Table I). The second relates to the incidence of typhoid fever in the inoculated and uninoculated in Lord Methuen's column at the Modder River, South Africa, from December, 1899, to March, 1900 (vide Table II.).

TABLE I.—*Showing the Incidence of, and Death-rate from, Typhoid Fever in the British Army in India during the Year 1901.*

—	Average strength during the year	Cases of typhoid fever.	Deaths from typhoid fever.	Incidence rate.	Death-rate.
				Per cent.	Per cent.
Uninoculated ...	55,955	744	199	1·33	0 36
Inoculated... ...	4,883	32	3	0·66	0·06

We learn here that antityphoid inoculation reduced the incidence-rate of typhoid fever by half and the death rate by five-sixths. A further point of interest in the table is its testimony to the duration of the protection afforded by antityphoid inoculation. It may be premised in this connexion that the number of inoculated in the table represents a falling off of 1100 from the figures of the previous year, a falling off due to the practical suspension of antityphoid inoculations. It follows that the statistics here in question refer almost exclusively to men inoculated in 1898, 1899, and 1900. So far as they apply to men inoculated in 1900 confirmation is furnished to the statistics of 1900 which showed that the protection conferred by inoculation in 1899 showed no signs of diminishing in 1900 So far as the statistics of 1901 refer to a residue of the 4000 men inoculated by myself in India in 1898-99 they amplify previous statistics to the extent that they suggest that the protective effect of inoculation continues for a minimum of three years.

The second statistical record applies, as already mentioned, to Lord Methuen's column during a limited period of the

South African war. It was furnished by Surgeon-General Townsend, C.B.

TABLE II.—*Showing the Incidence of Typhoid Fever in Lord Methuen's Column at the Modder River, South Africa, from December, 1899, to March, 1900.*

—	Number.	Cases of typhoid fever.	Incidence rate.
Uninoculated	10,981	257	2·3 per cent.
Inoculated	2,535	26	1·0 "

It will be noted that Table II. testifies to a diminution of the incidence rate by more than half during the period of observation. It would seem legitimate, in view of the statistics set forth above and of previous statistics, to infer the continuance of a similarly diminished rate of incidence during the whole of these men's service in South Africa. It will be noted also that this table discloses nothing with regard to the case mortality of the inoculated and uninoculated attacked by typhoid fever. This omission is no doubt due to the fact that the sick were transferred to hospitals at the base and passed out of Surgeon-General Townsend's ken. We may probably, in view of statistics in Table I., *supra*, and of those included in my synoptical table, infer that there was here superadded to the diminution in the incidence rate of typhoid fever also a diminution in the death-rate.

Lower Seymour-street, W.

SOME REMARKS ON 50 CASES OF BILHARZIA DISEASE,

WITH SPECIAL REFERENCE TO THE CHARACTERS OF THE WHITE CORPUSCLES FOUND IN THE BLOOD AND URINE

BY S. R. DOUGLAS, M.R.C.S. ENG., L.R.C.P. LOND.,
CAPTAIN, I.M.S.,
AND
F. W. HARDY, M.B., B.C. CANTAB.,
MAJOR, R.A.M.C.

ATTENTION has been drawn by Coles to the presence of an excess of coarse-grained eosinophile leucocytes in the blood of a patient suffering from bilharzia disease. The presence in the Royal Victoria Hospital, Netley, of a large number of cases of this disease in soldiers who had served in South Africa afforded us an opportunity for making further investigations in connexion with this disorder.

Clinical symptoms.—In most of the cases the clinical symptoms were very slight, vague pains in the back being most complained of; only a few of the patients complained of frequent micturition and pain on passing the urine. When blood was passed it was most marked at the end of micturition and nearly all the patients stated that their linen became blood-stained from a drop or so of urine coming away after they had adjusted their dress. None of them complained of any rectal symptoms

Duration of the disease.—The duration of the different cases examined was from nine months to over two years and according to the patients no improvement had taken place since the onset. Many of them had had various drugs administered without the slightest effect.

Incubation period.—But little can be said with regard to the incubation of the disease; of 14 men of the Argyll and Sutherland Highlanders 12 first noticed the disease in January or February, 1901, while at Rustenburg or in that neighbourhood This regiment had been at Rustenburg since September, 1900, and its movements before that date were in the Eastern Transvaal.

Period of the year at which the disease first appeared.—An analysis of the data with regard to the season at which the first symptoms of the disease appeared shows that the disorder may probably be contracted at every period of the year.

Possible extension of the disease to other countries.—The circumstance that patients who contracted the disease in South Africa have already been invalided to Netley from India, Burmah, and Malta, stations hitherto free from the disease, shows that the ova of the parasite must have been widely disseminated over the globe by soldiers from South Africa, and it may be noted that this is in conformity with the fact that the endemic area of the disease in Africa has been widely extended by the movements of infected soldiers.

Remarks on the differential blood counts.—The films were in each case stained with Leishman's stain. The number of leucocytes counted was in each case at least 300, this number being considered sufficient in view of the large number of cases examined and the grand total of 16,149 leucocytes were counted. The blood of all the patients examined seemed to contain an excess of white cells. With the exception of Case 14 the percentage of coarse-grained eosinophile leucocytes was above the normal limits, the average for the whole series being 16 48 per cent. There were, however, great variations in the different cases, the extremes being Case 2 with 40 per cent. and Case 14 with 1·3 per cent. Of the remaining cases 20 (Nos. 1, 3, 4, 5, 6, 15, 20, 22, 23, 24, 30, 33, 34, 39, 45, 46, 47, 48, 49, and 50) [illegible] above 15 and in only two (Nos. 36 [illegible] below 6. The increase of the [illegible] been principally at the expense of the polymorphonuclears. Polymorphonuclear leucocytes were below the average percentage, the average for the series of cases being 44·58 per cent. The general impression was that these leucocytes were distinctly more granular than usual, the granules being both more numerous and of larger size and in some instances almost approached the [illegible] and 42) in which evidences of malaria were found—namely, pigment contained in some of the mononuclears in the former case and both benign and malignant tertian parasites in the other case—the figures were very high, 25 per cent. and 28·4 per cent. respectively; but in ten other cases (Nos. 1, 2, 3, 4, 5, 7, 10, 13, 31, and 39) the percentage was above 15 Many of the mononuclear cells contained a few red-staining granules Intermediary forms between lymphocytes and large mononuclears were numerous and it was often difficult to know into what category the cell should be placed. Doubtful cells were therefore classed as lymphocytes. Lymphocytes gave an average percentage of 25·76, different cases showing large variations. In only two (Nos. 14 and 43), where the figures were 43·9 per cent. and 42·6 per cent., was there a distinct increase, and in both of these cases the coarse-grained eosinophiles were very much less numerous than usual Included under the head of basophile were mast cells and their average number (0·503 per cent.) was rather above the average of normal blood. In no case, however, did they reach 2 per cent.

Taking the mononuclear leucocytes as one class and the polymorphonuclears as the other, the average percentages work out at 38 286 per cent and 61 569 per cent. respectively, this being approximately the proportion found in normal blood.

The urinary sediment.—The urine was in each case centrifuged, one portion of the deposit was examined without staining, another was made into films and lightly stained with Leishman's stain. The number of bilharzia ova varied enormously in different cases and also varied from day to day in the same case, the specimens in which most were found being often comparatively free from both cellular débris and blood. The amount of blood varied enormously—in some cases the urine was bright red, in others nothing was noticeable with the naked eye; many of the cases which contained much blood showed extremely few ova. Bladder epithelium was frequently present.

In all the cases examined the sediment contained many leucocytes which were, as a rule, extremely well preserved; by far the greater number of these were coarse-grained eosinophiles. In some cases no other sort of leucocyte was found after prolonged search and in the cases where they were least numerous this percentage never sank below 50; the other form of leucocyte seen was almost exclusively the polymorphonuclear, lymphocytes and large mononuclears being very uncommon. No explanation could be found for this striking predominance of the eosinophile over the other leucocytes and the only suggestion that can be given is that the irritation arising from the lesion of the bladder causes either the other leucocytes to change into eosinophiles or has some special attraction for this form of cell.

CONCLUSIONS.

1. *Histological characters of the blood.*—(*a*) The percentage of the coarse-grained eosinophile leucocytes is, with very

The total number of leucocytes counted was 16,149 The average percentages of various leucocytes were as follows: Eosinophiles, 16·486; polymorphonuclears, 44·58, lymphocytes, 25·76, large mononuclears, 12·526; and basophiles, 0·503

REMARKS ON URINARY SEDIMENT, &c

CASE 1.—Ova in the urine were not very numerous. With very few exceptions all the leucocytes in the urinary sediment were coarse grained eosinophiles

CASE 2.—Percentages were taken to nearest whole numbers Ova were very few. All the leucocytes seen in the urinary sediment were coarse grained eosinophiles

CASE 3.—Ova were numerous. The leucocytes in the urine were numerous, mostly coarse grained eosinophiles, but some polymorphonuclears were present.

CASE 4.—Ova were few. All the leucocytes seen in the urinary sediment were coarse-grained eosinophiles

CASE 5.—Ova were very numerous. The leucocytes in the urine were mostly coarse grained eosinophiles but polymorphonuclears and lymphocytes were also present

CASE 6.—Ova were fairly numerous The leucocytes in the urine were scarce, mostly coarse grained eosinophiles, some polymorphonuclears were present.

[illegible] leucocytes in the urine seemed to [illegible] rly all the leucocytes seen in the [illegible] a few polymorphonuclears were present.

[illegible] rous The [illegible] philes and [illegible] ie urinary [illegible] tes in the [illegible] lears were present.

CASE 12.—Very few ova were present in the urine.

CASE 13.—Ova were scarce; there was much blood in the urine. The leucocytes were not very numerous and were mostly eosinophile, but some polymorphonuclears were present.

CASE 14.—Ova were scarce

CASE 15.—Ova were fairly numerous The leucocytes in the urine were mostly eosinophiles

CASE 16.—Ova were very numerous The leucocytes in the urine consisted almost entirely of eosinophiles

CASE 17.—Two myelocytes were seen. Ova were very scarce and much blood was present The leucocytes in the urine consisted of [illegible] on [illegible] he [illegible] of the leucocytes found in the urine were eosinophiles.

CASE 35.—Some of the large mononuclears contained pigment granules due to malaria

CASE 40.—The patient was recovering from an attack of orchitis.

CASE 42.—Benign and malignant tertian malaria parasites were present in the blood

CASE 45.—There were very few ova Eosinophiles and polymorphonuclears were present in about equal proportions in the urinary sediment; a very few lymphocytes were seen.

CASE 47.—Very few ova were present The eosinophiles were slightly more numerous than the polymorphonuclears. A very few lymphocytes were seen.

CASE 48.—Very few ova were present The leucocytes were mostly eosinophiles, the remainder being polymorphonuclears with a very few lymphocytes

CASE 49.—Very few ova were present. The leucocytes were almost all eosinophiles

CASE 50.—Very few ova were present The leucocytes were largely eosinophiles.

few exceptions, much above the average percentage found in normal blood. (*b*) This increase goes hand in hand with a proportional diminution in the percentage of the polymorphonuclear leucocytes. (*c*) Less frequent is an increase of the large mononuclear leucocytes, and where this is present it is associated with a diminution of the lymphocytes.

2 *Histological characters of the white blood corpuscles in the urinary sediment.*—A very large proportion of the leucocytes found in the urinary sediment are coarse-grained eosinophiles, the remainder being almost all polymorphonuclears, lymphocytes and large mononuclear leucocytes being uncommon.

3. *Variations in the number of ova in the urine.*—The ova vary in number greatly from day to day; large quantities of blood and other cells are often present when but few ova can be found.

SOME INVESTIGATIONS ON THE URINE OF CHILDREN.

BY ARTHUR W. FULLER, M.D. EDIN.,
RESIDENT MEDICAL OFFICER, ROYAL HOSPITAL FOR CHILDREN AND WOMEN, WATERLOO-ROAD, S.E.

THE object in writing this paper is threefold: firstly, to estimate the average amount of urine passed in 24 hours by children of average health of the ages of six months up to 12 years inclusive; secondly, the estimation of the total urea usually passed in the urine of children when in health; and thirdly, the quantitative estimation of the purine bodies in the urine of children of the ages mentioned. The results obtained are recorded in a table and are in relation to age and to body-weight. A full and complete record of the diet has been kept during each experiment. The great bulk of the cases were taken from healthy workhouse children belonging to the parish of Lambeth, but a few cases were taken from the Royal Hospital for Children and Women, Waterloo-road, S.E. (only those beyond suspicion of disease being selected), and three of the children were private patients. The mode of procedure adopted in order to obtain the samples and to arrive at the estimation of the total urine passed by the child in the 24 hours was as follows. The child was required to empty the bladder at a given time—say, 12 noon. This sample was not saved, but all the urine passed up to, and including that passed at, the same hour next day was kept, well mixed, and a sample taken of the mixed urine. The urine total was measured and recorded in cubic centimetres. Each child was also carefully weighed at the time of the experiment. Urea is the chief nitrogen-containing constituent of the urine and its amount was ascertained by means of Gerrard's ureometer, all urine containing albumin being rejected except one sample which contained a very slight trace; this was boiled and carefully filtered before being tested. The purine bodies, although containing a comparatively small quantity of nitrogen, are of great interest from the point of view of proteid metabolism and the estimation of uric acid and I am not aware that they have been estimated systematically and in this manner before. The purine bodies used to be called xanthine bases or nuclein bases because they are derived from nuclein, or alloxuric bases because they contain in combination two radicles, one of alloxan and the other of urea. Latterly they have been shown to be derivatives of a substance called purine by E. Fischer. They consist of the following amongst others (purine $C_5H_1N_4$): monoxypurine or hypoxanthine, $C_5H_4N_4O$; dioxypurine or xanthine, $C_5H_4N_4O_2$; amido-purine or adenine, $C_5H_1N_4NH$; amido-oxypurine or guianine, $C_5H_4N_4ONH$; trioxypurine or uric acid, $C_5H_4N_4O_3$. Theobromine (dimethyl xanthine), caffein theine (trimethyl xanthine), substances which are present (in quantities varying from 1 to 3 per cent) in cocoa, coffee, and tea respectively, are also purine derivatives. Purine itself ($C_5H_1N_4$) has not as yet been discovered in the body.

The quantity of purine bodies found in the urine bears a direct relation to the amount of the purine contained in the food eaten and is also affected by the extent of the nuclein cleavage in the metabolic processes of the body. The former group have been named exogenous and the latter endogenous purine. The purine bodies may be fully precipitated by nitrate of silver in ammoniacal solutions or by cuprous oxide in the presence of sodium bisulphite. They exist in all forms of meat extracts and in flesh meats of all kinds. The potato and other vegetables, such as the beetroot, contain them. Oats also contain them. The specific actions of uric acid and the other purine bodies upon the various tissues of the body are of great interest and importance: (1) in relation to the question of diet in children during the early years of life; and (2) in regard to the cessation of the processes of growth, the maintenance of adult life, and the gradual decline of bodily activities.

The estimation of purine substances in food has been made by several observers—Kossel-Burian and Schur, Offer and Rosenqist, and more recently by Dr. I. Walker Hall of Manchester. Several methods have been devised for the estimation of uric acid which need not be described here. The method of Dr. Hall for estimating the total urinary purines is one which I have used and is as follows. (In the experiments recorded in this paper only albumin-free urine was used, but for other experiments if any albumin should be present it is necessary to precipitate and to remove it by filtration.) Two solutions are used:—No. I. solution consists of Ludwig's magnesium mixture,[1] 100 cubic centimetres; ammonia solution, 20 per cent., 100 cubic centimetres; and talc, 10 grammes. No. II. solution consists of silver nitrate, one gramme; ammonia, strong, 100 cubic centimetres; talc, five grammes; and distilled water, 100 cubic centimetres. To 90 cubic centimetres of the urine 20 cubic centimetres of No. I. solution are added. An immediate precipitate of the phosphates falls and the clear fluid remains. To 80 cubic centimetres of the clear fluid 18 cubic centimetres of solution No. II. are added. The resultant precipitate is a mixture of silver chloride and silver purine. The former body is dissolved by the excess of ammonia. The filtrate is shaken until all white flakes disappear and the finely granular yellow-white precipitate remains suspended. If the silver chloride is not entirely dissolved strong ammonia is added drop by drop and the solution well shaken until no AgCl remains. These two processes which have first been described are best carried out by means of the "purinometer." It consists of three parts: (1) a closed graduated tube, (2) a stop-cock with above of the same diameter as the upper tube, and (3) a small glass reservoir of known cubical capacity. The graduated tube is capable of being shut off from the broader part by the glass stop-cock. The upper part of the cylinder has a moveable glass-stopper. 90 cubic centimetres of urine are taken from the mixed urine of the 24 hours and poured into the graduated cylinder, taking care to have the stop-cock turned off. Solution I. is added and the resulting precipitate of phosphates is allowed to fall into the lower part of the tube by turning on the stop-cock. The time for the fluid to become quite clear varies, but is never less than five minutes and seldom over half an hour; the powdered talc greatly helps the precipitate to settle. When the phosphates have in this manner fallen to the lower end of the tube the stop-cock is turned off again and No. II. solution is added up to 100 cubic centimetres. The purinometer should be inclined vigorously backwards and forwards for about a minute in order to dissolve the silver chloride and to reduce the flakes to a finely divided precipitate. The apparatus is placed in a cupboard away from the light and then the number of cubic centimetres occupied by the precipitate is read off 24 hours later. Dr. Hall recommends waiting as long as this and I have followed these instructions, but I consider that this time is unnecessarily long. No tea or coffee was allowed during the experiment. Table I. shows the results which were obtained by the methods which have just been indicated.

This table gives a summary of the results of these investigations. It has been shown that in order to obtain reliable information regarding the amount of urine, urea, or purine bodies it is not sufficient to take one 24 hours' sample, at least *three* must be taken from each case. The variation is often considerable from day to day and the urea which on one day shows a high percentage on the following day (and perhaps because of this) may have dropped to a corresponding low ratio. This remark also applies to the amount of urea, which in many cases varies very considerably on different days, and the same applies to the purine estimation. In all, 63 samples have been taken from healthy children, so that the results have some claim to be regarded as fairly representing the normal urinary percentages, &c., of healthy English children.

---

[1] Mag. chlor. crystal, 110 grammes; ammonium chloride, 110 grammes; ammonia, 250 grammes; and water, one litre.

General conclusions.—The *amount* of urine of course increases with the growth and development of the body, but the amount of urine passed per kilogramme of body-weight (although presenting some variation in different individuals, due either to their constitution or their habits) will be found *not* to increase. The amount of urea passed per kilogramme of body-weight would appear to be increased about the second year, but after this it remains fairly constant up to the age of 12 years, and the increase at the second year is probably only due to the greater quantity and variety of the food ingested. The results of the investigations of the excretion of urinary purines show that the amount excreted per kilogramme of body-weight bears no relation whatever to the age or sex of the individual. And this is of great interest when it is coupled with the fact that there are comparatively great variations, pointing, as it does, to idiosyncrasies in this respect, and it may be of value as indicating hereditary and constitutional tendencies. The method adopted in this series of experiments has been as nearly as possible physiological. The children were fed on an ordinary and suitable dietary, were healthily employed, and had regular exercise. I consider that the results obtained from specialised dietaries are apt to be misleading on account of the production of aphysiological conditions.

It is interesting to note that these conclusions in respect to the total quantity of urine and urea contained in it are in general agreement with the results obtained by Dr. Churchill, professor of pediatrics in the Chicago Polyclinic[2] (vide Table II.). Dr. Churchill mentions the fact that American children excrete a smaller amount of urine than those of Germany and Austria and some other countries. The present observations show that the same remark applies to English children (or more correctly London children). Vierordt's[3] tables on this subject show an enormous difference in this respect, but as his percentages were based on a very small number of cases they cannot be regarded as final (vide Table III.). As tending to confirm this it is evident that even in adults the amount of urine passed in Germany and Austria is greater than in England and America. Salkowsky gives from 1500 to 1700 cubic centimetres as the average in Germany. Jaksch gives it as from 1500 to 2000 cubic centimetres in Austria. Landois and Stirling record the English average as from 1000 to 1500 cubic centimetres.

TABLE III.—*Vierordt's Table.*

Age.	No. of cases.	Average weight in kilogrammes.	Total urine in 24 hours, cubic centimetres.	No. of cubic centimetres for each kilogramme of body-weight.
3–5 boys ...	4	13·82	743	53·03
3–5 girls ...	4	14·73	708	48·0
6 boys	1	15·5	1209	78·0
7 „	1	22 42	1055	47 06
11 „	1	24·0	1815	75·64
13 „	1	32 69	788	23·12
—		63·0	1700 to 1800	28·0

Gautier gives that of France as from 1250 to 1300 cubic centimetres and Simon that of Americans as from 1000 to 1300 cubic centimetres. Herz,[4] after noting results from 60 children of both sexes from the ages of three to 14 years, found that from 500 to 1400 cubic centimetres was the average daily amount and Camerer found from 619 to 1034 cubic centimetres in individuals of from two to 11 years old. Parrot, Cruse, Camerer, Martin Ruge, and others state that from 200 to 500 grammes are the average diurnal quantity of urine passed by a child from one month to two years old. Dohrn and Martin Ruge state the newly born infant passes in relation to every kilogramme of body-weight four times as much urine as the adult. Holt[5] by combining the results of the investigations of Schabanowa, Cruse, Camerer, Martin Ruge, Pollak, Berti, Schiff, and Herter gives the following :—

TABLE IV.

Age.	Total urine.	
	Grammes.	Ounces.
First 24 hours	0 to 60	0 to 2
Second 24 hours	10 „ 90	½ „ 3
Three to six days	90 „ 250	3 „ 8
Seven days to two months	150 „ 400	5 „ 13
Two to six months...	210 „ 500	7 „ 16
Six months to two years	250 „ 600	8 „ 20
Two to five years	500 „ 800	16 „ 26
Five to eight years...	600 „ 1200	20 „ 40
Eight to 14 years	1000 „ 1500	32 „ 48

Urea.—In regard to the excretion of urea, Dohrn found 36 milligrammes of urea in the bladder of a child who was just born and Martin Ruge found the following quantities (grammes) during the first ten days of life: 0 07683, 0·2504, 0·1358, 0 1817, 0 2567, 0 2267, 0 2284, 0·16240, and 0·1505. Although the amount of urea is very plentiful up to the end of the first month (0 80 gramme per kilogramme of child) according to Parrot, and amounting during the third week to 1 gramme and 1·89 grammes, Dr. Fernandez Figueira[6] of Rio de Janeiro says we may conclude that the amount is 1·7 per cent and therefore less than in adults. Holt (1903) gives the following[7]: First days, 0 076 to 0 114 gramme; two to seven days, 0·140 to 0 660 gramme; one to two months, 0 90 to 1·40 grammes; three to five years, 13 09 to 14·01 grammes; and five to 13 years, 16·0 to 21·03 grammes. This estimate gives a considerably lower amount in the case of children of from three to five years than I have found to be the case and also a slightly lower estimate in children of from five to 13 years of age. Churchill found that not only were the average percentages for children higher than the average given for adults, but individual cases show a remarkably high percentage of elimination of urea, no less than eight children having over 3 per cent., the highest being 3 7 per cent, and this observation exactly agrees with the results obtained in the present investigations. Purdy and Foster also state that the excretion of urea in children is relatively higher than in adults. The low percentage of early infancy is, of course, due to the quiescent state of the child, but Martin Ruge reports wide variations in single specimens during the first ten days of life varying from 0·6 to 1·9 per cent. Schiff also gives wide variations, from 0·28 to 1·7 per cent., during the first 14 days. Vierordt's observations give from 1·1 to 2 per cent. for older children from three to 12 years old, but this result is based on only seven cases. Vogel[8] pointed out in 1863 that although the absolute quantity of urea passed by both women and children is less than by men yet the relative quantity passed by children in relation to the body-weight of the adult is greater. According to Uhle's[9] observations (1859) children pass for each kilogramme of their body-weight as follows: Urea, from three to six years about 1·0 gramme; from eight to 11 years about 0·8 gramme; and from 13 to 16 years about 0·4 to 0·6 gramme. This result as regards the ages eight to 11 years is in accordance with mine. Vogel says that the quantity naturally varies in different persons and in the same person at different times according to the bodily constitution and the nature of the diet and the activity of the nutritive functions of the individual. Moreover, these numbers do not include the maximum and minimum quantities of urea which occur in certain cases in perfectly healthy persons. Neubauer[10] in 1863 proved that the urine of a healthy man fed on a mixed diet contained from 2·5 to 3 2 per cent. of urea and that the amount varied directly as did the weight of body and quantity of food ingested, but numerous other investigations give from 30 to 40 grammes = 0·37 to 0·60 gramme per kilogramme of body-weight. Lehmann found 58 grammes of urea in 24 hours under a purely animal diet and this dwindled to 0·15 gramme on a non-nitrogenous diet. The urea does not wholly disappear even when no food is taken.

It is beyond the scope of this paper to discuss the origin of the urea and the causes of its variation, though it may be mentioned that Franque of Würzburg as far back as 1855 established that it was affected by the amount of nitrogenous food ingested and Vogel stated in 1863 that the amount of urea was an approximate measure of the degree of metamorphosis of proteid compounds going on in the body; both these views are probably correct.

Purine bodies.—The conclusions arrived at by me as to the amount of the purine bodies excreted have been briefly referred to in an earlier part of this paper. The results recorded show that although there is much variation per kilogramme of body-weight, yet this variation bears no relation to the age of the child. Uric acid is included in the purine series and Holt says in the last (1903) edition of his work (p. 640) that few observations have been made on the elimination of uric acid, but all authorities agree that it is much higher in the newly born than at any subsequent period of life.

Proportion of uric acid to urea.—Martin Ruge gives in the newly born, 1 to 14; Herter gives—under one year, 1 to 60; from two to five years, 1 to 50–70; and from two to 15 years, 1 to 45–60.

Concluding remarks.—In presenting the result of these investigations I feel bound to allude to the fact that, since medicine is not an exact science, it is important for physicians in this country to have data to refer to which have been obtained in this country, for however much we may owe to foreigners and to their statistics it is impossible, as the accompanying tables show, for them to be accepted as indicative without modification of the normal condition of things that obtains in the people of our own country who are not only of another race but, generally speaking, live under other conditions.

It is interesting to find that the results of the present inquiry nearly agree with those obtained from American children by Dr. Churchill. The remarks of Dr. Figueira cannot be passed by when he says that the diseases of the urinary system and of other organic local affections demand a practical knowledge of clinical urology, and this chapter of infantile semeiotics is as important as it is generally neglected, either because it is believed erroneously that disturbances of the urinary functions are infrequent in the child or because of the usual difficulty in collecting the urine for examination *Dr A W Gilchrist*,[11] *Dr H Harper*,[12] Mr Edwy G Clayton,[13] and others have recently pointed out that the urine of tuberculous patients shows unusually low proportions of phosphates and of urea. Dr Harper strongly advocates the use of urea to supply the deficiency, but I cannot say that I have ever seen any improvement from its use clinically The diminution of nitrogen in the urine may be taken as a proof that there is an interference with proteid metabolism, but it seems to be a crude therapeutics that would supply it in the form in which it is excreted and what may be a valuable hint from nature becomes of no value practically if it is to be interpreted after this fashion I feel confident that the estimation of the urea and purine bodies as well as of the other constituents of the urine will be of service in the determination and treatment of certain diseases and I am hopeful that this contribution towards the subject may be of use in the evolution and advancement of our knowledge of those early chemical changes that take place in the human organism in the course of disease, antecedent as they are to those gross lesions with which the pathologist becomes so familiar and after all are oftentimes only monuments of the present deficient state of knowledge of the slow and subtle processes whereby those organic changes have been produced

SOME OBSERVATIONS AND COMPARISONS ON THE DIETETIC AND DRUG TREATMENT IN CHRONIC PULMONARY TUBERCULOSIS

By D LLOYD SMITH, M B LOND, D P H
R C P & S LOND,
RESIDENT MEDICAL OFFICER MANCHESTER SANATORIUM,
BOWDON CHESHIRE

THE treatment of pulmonary tuberculosis in sanatoriums is a topic which has excited a great deal of attention The recent literature on the subject has grown to immense proportions and many so called "specific" drugs have been brought forward and advocated by various authorities Some of these are tried, soon given up and are never heard of again Naturally one cannot deal here with such a wide subject. I know fully that there may be little new in what follows and it is mostly for the sake of giving a general survey and of showing the value of the various treatments adopted in the Manchester Sanatorium (which my personal experience has led me to consider the most satisfactory) that I have ventured to bring forward the following Of course in criticising the results of sanatorium treatment it must always be borne in mind that to secure the best results one must be careful in the selection of cases and this is a difficulty with the working classes Early cases are the only ones likely to be cured but there is sometimes the difficulty of making an early diagnosis and frequently cases come too late The existence of tuberculosis cannot always be confirmed by the detection of the specific bacilli in the sputum, as frequently expectoration is absent or it may consist of mucus which may not give positive results even after repeated examinations I have made it a condition in choosing these cases that the tubercle bacillus was found in the sputum, all being fair examples of the "consumptive' patient in whom there was every reasonable hope of establishing an arrest of the disease Moreover, they were in the sanatorium at the same time during the early part of the year and so were subjected to the same climatic conditions and diet

A more practical end will be attained if the diet in use at Bowdon (*vide* diet chart) is first considered and then the cases arranged under the various kinds of treatment employed It is a very remarkable fact that under the influence of the open air treatment and a judicious diet most of the well known symptoms disappear altogether, or, at least, are greatly modified without any drug treatment

The accompanying diet chart compares very favourably with that in use in some of the best sanatoriums The milk at Bowdon is supplied by contract and has to be sterilised or boiled before being served unless otherwise ordered The only comment to be made is that the milk supply to a sanatorium should be above reproach or suspicion so that sterilisation should not be necessary

In looking over the statistics and results of the various sanatoriums the nomenclature in use does not quite tally, so that it will be better beforehand to explain that in use at Bowdon To make the statistics of public sanatoriums of greater value a system of classification according to the stage of the disease on admission and result on discharge should be generally adopted The average stay at Bowdon of each patient is 91 days, who is then discharged in one of the following conditions

Cured, with no cough, expectoration, or physical signs, a temperature with a daily amplitude or excursion of 1° either above or below the normal, 98 4° F being the mid point, the pulse slower, regular, and full, the weight having increased in proportion to height and age, and in the case of women the menstruation regular

Much improved, with no expectoration, very slight cough, physical signs limited to slightly exaggerated breathing over the affected area, with temperature, pulse and weight as above, and ability to return to work as before

Improved, with only a slight cough present, scanty expectoration, no moist sounds in the chest, and a satisfactory temperature, pulse, and weight.

Stationary, with a cough present, scanty expectoration, physical signs confined to the same area and of the same character, and a regular temperature and pulse and increased weight

Worse with no amelioration of the symptoms and the disease extending

Table I gives the results of nine cases treated with an emulsion of creasote (five minims) three times a day, cod liver oil and malt being given in addition No other medicine was given to the above patients A few of them suffered from nausea and vomiting, the creasote mixture being then stopped or only half doses given The majority of these at the Manchester Sanatorium find no inconvenience from the creasote and take it well, in some the "oil and malt' has to be stopped owing to its causing indigestion or diarrhœa, but is continued on the abatement of such symptoms Here there are cases in all stages of the disease, five were discharged as stationary and two worse, the last having increased considerably in weight

Table II gives particulars of six cases treated with guaiacol administered as a pill (three minims) three times a day, "oil and malt being given as well The pills were first given in the usual white coated form, but it was observed that they were sometimes passed unchanged, this was also noticed when an enema had to be given One might argue on this score that the pills were too hard or badly made and not a fair test, *to obviate this uncoated pills were given* It is difficult to detect these in the fæces as being almost of the same colour, but undoubtedly some are dissolved and absorbed In this table the results are most favourable, the increase in the patients weight being far above the average, which is generally about 10 pounds, but the majority of the cases were in the first stage of the disease

Table III gives particulars of six cases treated with liquor arsenicalis (B P) only, no "oil and malt' being given Arsenic was given *in the form of the simplest* mixture with rose water, the dose being gradually increased from three to 15 minims (in some cases) three times a day after meals It was observed that no idiosyncrasy to the drug was shown in any of the patients and none showed symptoms of arsenical poisoning, a few only exhibited prodromata such as suffused conjunctivæ, increased nasal secretion, and sternutation, very few exhibited gastric symptoms The presence of arsenic was subsequently proved in the urine of some of the patients by *means of Marsh's and* Reinsch's tests I may add that I found in the routine examination of the chests that the moist sounds "dried up' sooner and assumed a more crepitant character at an earlier period in the patients taking this drug than in the "control' cases in the sanatorium It will be noticed that in this table the highest gain in weight is 6¾ pounds One is led to ask what would the increase be if the "oil and malt' had been given in addition In one patient (No 3) the disease was confined to the *right apex and in the early stage* the increase in weight being only one and three-quarter pounds and the patient being discharged as "cured,' and one can truly say so of this case

Much of the fat "put on" is probably of little use to the patient and disappears rapidly when he returns to the ordinary conditions of life and work, and one should not forget that to make a patient fat and to make him strong are not necessarily the same thing. *The end in view in open-air treatment of the working classes is to place the patient as nearly as possible on his former wage-earning basis.*

Table IV. gives the results of eight cases treated with a simple mixture of nux vomica, gentian, and acid, no "oil and malt" being given. The results in this table compare most favourably with the others and the gain in weight was most satisfactory, showing that the digestion and absorption of certain constituents of the food have been thorough and the increase in weight due entirely to an improved metabolism in the tissues generally, thus making a physiological use of

DIET CHART OF MANCHESTER SANATORIUM.

Meal and time.	Sunday.	Monday.	Tuesday.	Wednesday.	Thursday.	Friday.	Saturday.
6 30	Half-pint of hot milk and cocoa.	Same as Sunday.	Same as Sunday.	Same as Sunday.	Same as Sunday.	Same as Sunday.	Same as Sunday.
Breakfast, 8.30.	Eggs.	Cold ham.	Fish, brawn, or eggs.	Cold ham.	Fried bacon.	Cold ham.	Fish.
Lunch, 10.15.	Half-pint of milk and bread-and-butter or bread-and-treacle.	Same as Sunday.	Same as Sunday.	Same as Sunday.	Same as Sunday.	Same as Sunday.	Same as Sunday.
Dinner, 12.30.	Half-pint of milk, roast mutton, potatoes, and boiled pudding.	Roast beef, two vegetables, and milk pudding.	Roast mutton, two vegetables, and milk pudding and fruit.	Roast beef, Yorkshire pudding, two vegetables, and milk pudding.	Roast mutton or stew, two vegetables, and milk pudding.	Minced or cold meat and fish, potatoes, and milk pudding and fruit.	Roast beef, two vegetables, soup, and milk pudding.
Tea, 4 30.	Tea, bread-and-butter, jam or cheese, and eggs.	Same as Sunday.	Same as Sunday.	Same as Sunday.	Same as Sunday.	Same as Sunday.	Same as Sunday.
Supper, 7.30.	Porridge and half-pint of milk.	Varied by soup.		Coffee and bread-and-butter.			
9.30	Half-pint of hot milk.	Same as Sunday.	Same as Sunday.	Same as Sunday.	Same as Sunday.	Same as Sunday.	Same as Sunday.

The diet is slightly varied according to the season.

the foodstuffs supplied rather than the plethoric storage of excess material.

Table V gives the results of six cases treated with urea (one gramme three times a day flavoured with five minims of spirit of chloroform), no "oil and malt" being given, and Table VI gives the details of analysis of the urine of three of the cases. It was very doubtful from the first whether one of these cases (No. 6) was tuberculous, the sputum was examined on ten or 12 occasions but with a negative result. The physical signs in the lungs showed nothing adventitious, the case was, however, kept as a "control" for the other "urea" cases throughout. None of these cases showed any loss of appetite, nausea, or vomiting, which, according to Dr H. Harper, is an indication against urea. From a study of these cases one cannot but agree *in toto* with Dr S. Vere Pearson's results on the patients at the Brompton Hospital. In the first case only can anything like a favourable result be said to have been obtained.

TABLE III.—GIVING THE PARTICULARS OF SIX CASES TREATED WITH ARSENIC ONLY, NO "OIL AND MALT" BEING GIVEN.

No. of case	Sex	Stage and extent of disease	Tubercle bacillus	Expectoration	Cough	History of hæmoptysis	Temperature (Fahr.)	Pulse	Condition of nutrition.	Anæmia and menstruation	Gain or loss of weight in pounds	Result and remarks

A 0 = Anæmia absent. A + = Anæmia present. M R = Menstruation regular. M I = Menstruation irregular. M 0 = Menstruation in abeyance. N S P = Night sweats present. N S 0 = Night sweats absent. + = present.

From the above cases and those now given urea in the wards it appears to have no influence whatever in the progress of the disease one way or the other. If urea is going to do any good an improvement should show itself within three months. The doses given were one gramme three times a day, increased to two grammes three times a day; these are not such large doses as Dr. Harper uses. Now as to the diuretic action of urea (*vide* Table VI.). A daily estimation of the urine was made in Cases 1, 2, and 6; the urine was most carefully collected and analysed. Nothing was given for the first 21 days in the way of drugs or emulsion of oil and malt. Then the patients were given urea, one gramme three times a day, and the urine was collected and analysed as before for 26 days. The apparatus used for the estimation of the urea was Southall's ureometer. In Case 2 only is the output of urea less than that which was administered by the mouth. This I cannot account for, as there was nothing abnormal or adventitious in the urine analysis. Undoubtedly urea must be excreted in some other way than as urea, as the amount of urea "put in" does not show itself in the urea "put out." I was always led to believe that urea induced diuresis, but my observations are not in accordance with this; for the first few days it may be so, but the action soon passes off. In Table VI. it will be seen that in Cases 1 and 2 the average quantity in cubic centimetres per diem of urine secreted is much below that when no urea was taken, whereas in Case 6 (control) the difference is little (about 42 cubic centimetres).

TABLE VI.—*Giving the Particulars of the Urinalysis of Cases 1, 2, and 6.*

No. of case.	Tubercle bacillus found in sputum.	Non-urea period (21 days).			Urea period (three grammes per diem 26 days).		
		Average quantity in cubic centimetres.	Average specific gravity.	Urea, grammes per litre (average).	Average quantity in cubic centimetres.	Average specific gravity.	Urea, grammes per litre (average).

We will now take the "headings" of the accompanying tables seriatim.

Expectoration.—It is remarkable how those patients who on admission expectorate profusely after the first week or two practically cease to do so and those admitted with scanty and purulent sputum retain it for a longer time. At the sanatorium no expectorants or other drugs are given except in doubtful cases in which the chest is full of coarse moist sounds so as to discern between the transitory and persistent ones.

Cough.—This symptom persists longer than any other and is generally the last to disappear. Until lately almost every patient who had a "troublesome cough" was given syrup of codeine. No doubt this symptom in most cases is a "habit" and will soon disappear if the patient is told to resist the "temptation" to cough and a little moral and assertive persuasion is used on the part of the medical attendant.

Hæmoptysis.—In 17 of the above 35 cases this was present before admission and in only two of them can I find a history of hæmoptysis since admission, and, curiously enough, these were two taking urea. In my experience this is not a very alarming symptom and in only one case do I remember it to be recurrent and persistent. This patient was given the usual drugs, such as ergot, hamamelis, capsules and inhalations of turpentine, adrenalin chloride, and injections of gelatin subcutaneously; none of these appeared to have any permanent effect and the patient did quite as well by absolute rest in bed and liquid diet. Several blood examinations were made and it was observed that there was marked eosinophilia during and after the attacks of hæmoptysis. One is very apt to be surprised in the blood counts of the consumptive, as it is the unexpected that happens. I hope shortly to publish some further observations on this point.

Temperature.—This is always taken by the oral method and for all practical purposes appears to be quite satisfactory. The rectal method is not liked at all, being most disagreeable; the patient will not put up with it for long, and after reading the article on the Comparative Values of the Various Methods of Observing the Temperature by Dr. F. W. Burton-Fanning and Dr. S. Gurney Champion[1] one is inclined to give it up altogether. As a general rule a patient is admitted with an elevated temperature, about from 99·5° F. to 100°, but after a few days' complete rest in bed and the "Liegehalle" it soons settles down and remains about 98·8° or lower. It must not be forgotten that the temperature of phthisis is one of extremes. A low one is quite as indicative of phthisis as a high one and there are plenty of patients with no fever at all. If the temperature be a "swinging" one a "mixed" infection is the cause and these are mostly in the third stage of the disease. Any sudden rise in temperature is mostly due to nervous influence and in women to the menstrual molimen. Pyramidon has been given in cases of a "swinging" temperature above the normal line. The usual dose is five grains in an ounce of chloroform water at 3 P.M. and when the temperature is taken at 6 P.M. it is found to have come down, but not always. It is very seldom, indeed, that any antipyretic is required; on many occasions it has been found that a case with a temperature excursion of 3° (from 97° to 100°) has settled down to a regular line (with an excursion of 1°) when taken out to the "Liegehalle." *One can safely say that the amelioration of symptoms is in the inverse ratio to the amplitude or excursion of the temperature, and the course of treatment adopted should be to contract the daily range of temperature.*

Pulse.—More stress undoubtedly ought to be placed on the frequency, regularity, and tension of the pulse. As the pulse returns more to the normal it coincides more or less with the disappearance of the physical signs and is a better guide to the course of the disease than the temperature.

Anæmia.—I have made over 100 blood examinations and counts and in only about 5 per cent. have I found the hæmoglobin below 85 per cent. In these cases the condition of the mouth and teeth, and consequently that of the stomach, were anything but desirable and this mostly arises from oral sepsis. In several cases it has been noticed that after the extraction of from 12 to 20 teeth the patient has "put on weight" at a most astonishing rate, so the Chinese proverb that most "people dig their graves with their teeth" is not quite true in every respect.

Menstruation is in abeyance in only about 40 per cent. of the cases admitted and is interdependent upon the general condition of the body and when this improves the menses reappear.

Night sweats.—I have never had occasion to prescribe any drugs for the symptom as it disappears before the end of the first week.

One can but conclude from the accompanying tables and the foregoing remarks that the diet is of as paramount importance as any of the active principles of any mixture or drug given. In tuberculosis there is a wasting of subcutaneous fat, but the main feature is wasting of the nitrogenous elements of the muscles. A meat diet supplies a direct physiological want and the materials are "ready-made" for rebuilding the skeletal as well as the cardiac muscle which is also involved. This latter point is shown by the direct improvement of the circulatory condition as the muscular system recovers. All patients, however, should not be given the same amount of food and we can never be quite certain how any given individual will react to a particular kind of food. The diet should be modified to a certain extent for patients with gastric disturbance. With an abundant and mixed diet cod-liver oil is not necessary. The object in view is not to make the patient a "flabby breathless mass of fat," but to turn out a thoroughly solid, robust individual. A gain in weight is by no means everything, as this frequently occurs without an improvement in the pulmonary condition, and when this happens the selection of the diet is of great interest and the supervision and vigilance of the medical attendant are imperative. This latter point is one of the secrets of success in the sanatorium treatment of pulmonary tuberculosis, or, to put it concisely, "the ability to interpretate the individual variations in metabolism."

I should like to take this opportunity of expressing my thanks to the honorary staff for their permission to publish these results and especially to Dr. S. Moritz and Dr. K. Renshaw for their kindly help and advice.

Bowdon.

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

UROTROPIN IN THE PYURIA OF TABES DORSALIS.

By Walker Overend, M.A., M.D. Oxon., B.Sc. Lond.,
LATE SENIOR PHYSICIAN TO THE TOTTENHAM HOSPITAL AND RADCLIFFE TRAVELLING FELLOW.

The following case presents some points of interest. The patient, who was 36 years of age, exhibited the classical symptoms and signs of locomotor ataxia—occasional lightning pains, loss of knee-jerk, muscular incoördination, and vesical troubles. About April, 1899, he first noticed that the bed was wet of a morning, and soon afterwards the urine began to dribble during the day. It gradually commenced to run faster, until after a few months he never passed it at all in a natural manner but suffered from complete incontinence. He was compelled to wear an indiarubber urinal constantly. In the spring of 1900 he resigned his situation and went to live at the seaside. In March, 1901, he consulted me, but not for treatment of the bladder condition, inasmuch as he considered that to be hopeless and incurable. He had, as an out-patient, attended one of the special London hospitals for several years. I persuaded him to take a mixture containing ergot for a time but it proved useless. I then recommended eight grains of urotropin daily but he did not persevere with it. In September, 1901, he contracted influenza but recovered after a few days. The urine was ammoniacal and contained much pus. He was then passing nearly two pints into the urinal during the night and sleep was restless and disturbed. The ignominy of the wretched condition preyed upon his mind and he was morbid, depressed, and hypochondriacal. The vesical weakness in consequence became aggravated. I emphasised the necessity of resuming the urotropin and of taking it regularly for some months, and, irrigation being declined, assured him that the urotropin would greatly benefit him. In February, 1902, he stated that eight grains of urotropin had been taken daily for five months and that he felt much better. There had been no sign of hæmorrhage. The urinal was now practically dry at bedtime; he passed on his own initiative about two pints without pain during the day and the urinal in the early morning contained less than three-quarters of a pint. Moreover, he slept well and was looking out for some employment. One day in January he experienced—for the first time in two years—the desire to micturate. Since then he has learnt to ride a bicycle and he makes use of the machine in his new situation. The urine is free from pus and albumin and has an acid reaction which it retains even after standing for 24 hours. The urinal contains not more than half a pint of urine in the morning and only a few drops at bedtime. I suggested that he should continue the use of the urotropin until the dribbling ceased.

The regular administration of other vesical disinfectants such as salol might have led to equally good results and it seems reasonable to attribute a share of the improvement at least to the asepsis produced by the diurnal exhibition of the drug. The presence of a normal urine within the bladder with the absence of pyuria gave the sphincter an opportunity to recover its tone and the *detrusor vesicæ* its power. The restoration of physical tone and general mental equilibrium —a result of much exercise in the open air—no doubt assisted and favourably reacted upon the beneficial action of the urotropin. The addition of from one-fiftieth to one-hundredth of a grain of strychnine to the urotropin would probably facilitate the effect. The same combination may be suggested for the chronic vesical catarrh and pyuria of enlarged prostate and of diabetes as well as that of hemiplegia and senile debility.

Clacton-on-Sea.

CASES OF STOKES-ADAMS DISEASE (?).

By Isaac Crawford, L.R.C.P. & S. Edin., L.F.P.S. Glasg.

Eight years ago I attended a woman during an attack of pneumonia. She was above medium height, married, of sallow complexion, and very thin. There was nothing about the pneumonia to call for special comment, save that resolution was somewhat delayed.

At the end of the first week of the illness, having been hurriedly summoned, as she was supposed to be dying, I found her pulseless at the wrists and quite unconscious while her breathing was imperceptible. There was a faint, slow flicker to be detected with difficulty in the region of the cardiac apex. Injections of strychnine and digitalin were employed and heat was applied to the extremities and præcordia. She slowly revived, the heart-beats gaining in strength and rhythm until the heart behaved in its customary manner. On inquiry her friends said that the oncoming of unconsciousness was gradual. She had five similar attacks, there being an interval of several days prior to the last which proved fatal. Digitalis was given and curiously enough it was stopped about a couple of days before the last attack. Whether that contributed to the fatal result it is hard to say. In the intervals the heart was normal, no murmur or irregularity being observable. There was no history of any previous similar attacks.

About the same time I attended another patient whose heart behaved in a manner somewhat similar to the above. She was a primipara whom I delivered with instruments under chloroform. There was some hæmorrhage but not enough to be dignified by the name of post partum hæmorrhage. She then for no obvious cause passed gradually into a state of unconsciousness. Her pulse became slower and weaker and finally could not be felt at the wrists; her breathing could not be perceived; her cheeks became white; her limbs grew cold; and the fingers could not detect any sign of life at the cardiac apex. She lay in bed as motionless as if she were carved out of marble. Similar steps towards restoration were taken as in the previous case but I had to leave her still unconscious. Early in the morning I called again at the house and to my great relief I found her in excellent spirits and condition. She had recovered shortly after my departure.

There are references to the above condition in some of the text-books but nothing clear or explicit. I am unable to offer any explanation of the phenomena now described.

ROMFORD UNION INFIRMARY.

A FATAL CASE OF TETANY IN ASSOCIATION WITH DILATATION OF THE SMALL INTESTINE.

(Under the care of Dr. Dudley G. Greenfield.)

A married woman, aged 33 years, was admitted into Romford Union Infirmary under the care of Dr. Greenfield on August 29th. She had had three children, the youngest of whom was nine months old. About 12 days *before admission* she had been seized with vomiting and had been steadily getting worse. She had previously had no serious illnesses but for some weeks she had been badly fed and cared for. The bowels had been relieved twice during this time on the administration of an enema. On admission the patient had a very worn appearance and complained of lack of sleep owing to the vomiting. She had no acute pain at any time. The vomiting was distressing and very frequent. The vomit was distinctly fæcal in odour and in appearance it was very like a characteristic typhoid stool. The abdomen was considerably distended and tympanitic on percussion, the normal areas of dulness being preserved. It moved fairly well on respiration, no pain was caused on palpation, and no tumour could be felt. The abdominal wall was not in the least rigid and no peristalsis was visible The bowels had been relieved two days previously after an enema and the patient's general condition was fairly good. A soap enema was administered and a very large evacuation of clay-coloured fæces resulted and about half an hour afterwards the bowels again acted freely. The patient expressed great relief and said that she "felt a different woman." The distension of the abdomen was considerably less. She was given albumin water only by the mouth and plain water when thirsty. Five grains of calomel were given but she vomited shortly after. In the evening she was more comfortable, the vomiting was less, and the bowels were moved slightly after an enema. The tongue was moist, the pulse was good, and the abdomen was only slightly distended.

On August 30th the patient had passed a good night and felt much better as she had not slept for several days. The vomiting was only occasional. The vomit had lost its fæcal odour and was only bilious. There was a good result from an enema, the fæces being yellowish and loose and no longer clay-coloured. Another five grains of calomel were given without result. The abdomen was said by the patient to be of about the natural size. Albumin water was still the only food given and she had also ten grains of salol every four hours. In the evening she had two typical attacks of tetany, involving the hands, the feet, and the face and lasting about half an hour on each occasion, giving the patient much alarm. The marked abatement of symptoms, the disappearance of the fæcal odour from the vomit, the four actions of the bowels, and the approach to normal of the last motion all seemed to negative a diagnosis of intestinal obstruction other than that due to impacted fæces. The possibility of a gastro-intestinal fistula was considered and some disease of the pancreas was suggested by the whitish fæces but nothing could be felt on deep palpation of the abdomen. On the 31st the vomiting had ceased entirely and the bowels acted freely after an enema. The pulse was good, about 90, and the temperature was slightly subnormal. She had another attack of tetany lasting about 40 minutes. On Sept. 1st the patient had slept well after an injection of morphia given for the attack of tetany on the previous evening. There was no return of the vomiting and she took plenty of albumin water and fluid by the mouth. She was also given nutrient enemata of starch, eggs, salt, and milk to eight ounces every six hours, but the bulk had to be reduced owing to a bad tear of the perineum (not recent) and difficulty in retention. The bowels acted when the rectum was washed out with saline solution preparatory to the administration of the nutrient enema. The only adverse symptom at this time was the subnormal temperature, but the pulse was good and the extremities did not feel cold. On the 2nd the bowels were opened after the wash-out of the rectum in the morning. The albumin water was well retained as were also the nutrient enemata. In the evening she became very cold and collapsed, but improved again when some stimulant was administered. On the 3rd the patient was better again. The food given by the mouth was increased and the nutrient enemata were administered only twice daily. She took one and a half pints of peptonised milk, two ounces of pounded beef, some essence of beef, beside one pint of albumin water and retained it all. On the 4th her appearance had improved considerably, her face being much fuller. The pulse was good but the temperature was still slightly subnormal. Slight peristalsis was visible in the morning and in the afternoon the vomiting returned. On the 5th the patient had vomited frequently in the night, small quantities of bilious material being brought up. The bowels were moved several times quite naturally; the fæces were loose but normal in appearance, no blood or mucus being present. Peristalsis was again seen in the morning and her friends were advised that an operation would probably be required. In the afternoon, however, she became rapidly worse and died unexpectedly.

Necropsy.—A partial examination was permitted. On opening the abdomen some very distended coils of small intestine lay in front, matted together by some tough adhesions. These proved to be the upper part of the jejunum, the lower half of the jejunum and the ileum being empty and contracted. The junction of the distended and contracted portions was matted firmly down behind, close to the root of the mesentery. A finger passed down from above easily went through the point of apparent obstruction and that before the positions of the parts were much disturbed. On unravelling the coils no cause of obstruction could be determined. There was no fibrous stricture and no evidence of dragging or strangulation could be demonstrated. There was very slight capillary injection of the lowest end of the distended portion but there was no extravasation of blood, no lymph, or any sign of recent peritonitis. The pancreas was apparently healthy and the peritoneum showed no hæmorrhages or fatty masses. The stomach was not dilated and was free from any sign of ulceration. The rest of the abdominal viscera and the heart were quite normal in appearance.

Remarks.—From the post-mortem examination it is clear that the primary trouble was acute dilatation of the upper part of the small intestine. No obstruction could be discovered although the patient had old peritoneal adhesions and seeing that the bowels were opened well on each day that she was in the infirmary (eight days in all) and that on the last two days the bowels were opened naturally several times, no obstruction was probably present. Was this then a paralytic distension? The occurrence of tetany was very interesting in a case of this sort. It was fortunate that no operative interference was attempted as the utmost that could have been done was to have relieved the distended bowel and any attempt to arrive at the point of apparent obstruction would have been useless and impracticable owing to the dense bands of fibrous tissue. The post-mortem examination proved that the suspicion of pancreatic disease as a cause of these conflicting symptoms was unfounded.

The case came under my care while doing the work of Mr. J. A. Fraser of Romford and I am indebted to him for permission to publish this account.

HERTFORD GENERAL INFIRMARY.

A CASE OF SUPPURATING HYDATID; INFECTIVE ENDOCARDITIS; ANEURYSM OF THE PERONEAL ARTERY.

FOR the notes of the case we are indebted to Dr. Gordon Moir, house surgeon.

The patient, a lad, aged 19 years, was admitted to the Hertford General Infirmary on June 18th with the following history. His occupation was gardening on an estate in Hertfordshire, where he had lived all his life. His family history was very good, but one sister had recently died from phthisis. He had always been perfectly healthy except for typhoid fever which he had had nine years previously. He had never had any venereal disease and there was none in the family. In the beginning of May, 1903, he had a "feverish attack" and was laid up for a day or so, which he soon got over and resumed work. At the end of May whilst going to his work he was seized with sudden pain in the left leg and had to return home; he could hardly walk, the pain was so severe. He returned to work the next day and remained at it for three days, when the pain in his leg became so acute that he stayed at home and kept in bed with the foot raised. It was noticed at this time that there was a swelling in his leg; pulsation was not noticed till a week after its first appearance, when it had become slightly larger. The leg was swollen and painful.

On admission it was noted that the patient was a strong, healthy-looking lad, rather pale about the lips, and his voice was rather quavering. On the left leg, about two and a half inches below the head of the fibula on the postero-external surface, there was a hard, tense swelling of about the size of a fowl's egg. The skin was not adherent or reddened; it was slightly painful. The swelling was deeply situated, not moveable, and elongated. There was a distinct expansile pulsation. On compressing the popliteal artery pulsation was lessened, but there was no decrease in size; on releasing the artery the swelling regained its maximum pulsation in three or four beats. There was loss of pulsation in both anterior and posterior tibial arteries in the foot; the left ankle was somewhat swollen. The left leg measured 11½ inches and the right 10½ inches. The knee-joint was normal and there was no pain on flexion. There were no enlarged glands on the left side, but there were a few in the right groin. On examining his heart the impulse was in the fifth space just internal to the nipple line. Dulness extended to the second costal cartilage and to the right edge of the sternum. There were a loud presystolic bruit and a systolic murmur traceable to the angle of the scapula. On impulse there were an accentuated pulmonary second sound, a loud diastolic bruit in the aortic region, and a faint systolic bruit. The liver was not palpable; dulness did not extend below the margin of the ribs. The spleen was distinctly enlarged, coming down three and a half inches on *deep expiration.* It was not tender on palpation. The pulse was regular, of good volume, but rather dicrotic. The urine was of specific gravity 1008 and had no abnormal constituents. The left leg was raised to about 45° on pillows and kept at rest by sand-bags. On June 25th it was noted that the swelling had become more posterior, but its size and pulsation were the same as on admission. On the 28th there had been an intermittent pyrexia running up to 99° or 100° F. since admission. Treatment of the aneurysm was conducted [illegible] bandage applied firmly [illegible] r it, and ending at the r [illegible] ed every other day for about half an hour, when it became so painful that it was removed. On July 15th the patient became very anæmic; his pulse was decidedly water-hammer in type. On auscultation the systolic bruit in the aortic region was much more marked. The aneurysm had become much smaller, the pulsation was lessened, and it was situated nearly in the centre of the calf. On August 16th the patient complained of pain in the right hypochondriac region; his temperature had remained normal since July 15th. On August 17th the patient was seized with *sudden* pa[illegible] his dinner. He [illegible] dyspnœa then c[illegible] relief by sitting up and bending forward till his head rested on the bed. His pulse was 110 and his respirations were 30. He was given brandy. At 4 P.M. his temperature was 95°; the dyspnœa remained the same. He was given strychnine hypodermically and oxygen inhalation. On the 18th he dozed off and on during the night and he died at 3 P.M.

Necropsy.—On dissecting out the swelling in the left leg it was found to be a small saccular aneurysm of the peroneal artery, the deep fascia of the leg being tightly stretched over it. There was one pint of clear yellowish fluid in the left side of the chest and three-quarters of a pint in the right side. Both lungs were œdematous. No infarct was found in the lungs. With regard to the heart, the right ventricle was slightly hypertrophied; the rest of the right side was quite healthy. The left auricle was normal in appearance. There were numerous small vegetations on the mitral valves; the valves were thickened and distorted; the chordæ tendineæ in many places were missing; there was a small patch of ulceration on the left side. The left ventricle was enormously hypertrophied and dilated; the muscle was pale in colour and measured half an inch across. As to the aortic valve, on the right cusp there was a large fungating vegetation of about the size of a sixpenny piece; on the central cusp there were three small perforations; on the left cusp there was a patch of erosion and there was also erosion on the surface of the aorta corresponding to it. In the left kidney one large infarct was found and there were numerous smaller ones, giving rise to a "flea-bitten" appearance. The spleen was enlarged; its substance was very soft; at the upper end was a large cyst one inch in diameter which on being opened was found to be a suppurative hydatid. The liver was enlarged; in the right lobe were two large hydatid cysts containing daughter cysts and ordinary hydatid fluid. The rest of the viscera were healthy.

Remarks by Dr. MOIR.—The curious points about the case were the absence of all direct symptoms of the hydatid disease, as the enlarged spleen was accounted for clinically by the condition of the heart. During the whole time the patient was under observation he only complained of pain once which was in the epigastrium. Pressure in the splenic area seemed to cause no pain. The course of the case seems to have been, primarily, hydatid disease in his liver and spleen, the latter suppurating at the beginning of May (his "feverish attack"), and from this suppuration infective endocarditis was set up, which accounts for the rest of the symptoms. It was impossible to make a bacteriological examination of the various pathological lesions to see whether these were all due to the same organism.

ACTION FOR THE RECOVERY OF MEDICAL FEES.—At the Cardiff county-court on Sept. 30th Dr. Thomas Wallace of Cardiff sued the late proprietor of a Cardiff hotel for £27 for professional services rendered in 1901. Dr. Wallace had attended the defendant's housekeeper at the request of the defendant who had previously paid him for such attendance. The judge found for the plaintiff for the amount claimed with costs.

Reviews and Notices of Books.

Anleitung zur Durchführung bakteriologischer Untersuchungen für klinische diagnostische und hygienische Zwecke. (Guide to the Performance of Bacteriological Examinations for Clinical Diagnosis and Hygienic Work.) By Dr. LUDWIG KAMEN. Vienna: Josef Šafář. 1903 Royal 8vo. Pp. 311, with 12 plates and 118 figures in the text. Price, marks 8 40.

THIS is a useful, if rather voluminous, note-book which outlines the course in practical bacteriology at the Military School in Vienna and is intended for use at the bench. Following a short historical survey which serves as an introduction, the bulk of the book is divided into two nearly equal parts. The first, which comprises 135 pages, is devoted to matters of technique; the second, of 154 pages, deals with the chief specific bacteria considered in relation to the diseases with which they are associated. The first part is fairly full and comprehensive and opens with a short description of the morphology of bacteria in general and their structure, both physical and chemical. Next their growth and reproduction are considered and their biological activities and the end-products of their metabolism are described in a clear and concise manner. In this connexion the author gives an interesting table of the results obtained from acid- and alkali-forming bacteria grown in Petruschky's neutral litmus whey, showing the extent of the reaction in terms of normal alkali and acid respectively—bacillus typhosus, for example, forming from 2 to 3 per cent. of acid, whilst the bacillus pyocyaneus produces from 8 to 9 per cent. of alkali. Another table shows the result of the fermentative action of various micro-organisms upon certain specified compounds. Immunity and cognate subjects such as agglutination and hæmolysis are briefly, but at the same time sufficiently, discussed. Chapters III. and IV. are devoted to a consideration of microscopical optics and the microscope itself, together with accessory apparatus—the author, of course, remaining faithful to the instruments of Zeiss and Richert. The next seven chapters deal with technique proper and review in turn the methods of sterilisation, microscopical methods for the demonstration of bacteria, the artificial cultivation of micro-organisms, the immunisation of animals, and the preparation of toxins.

Many of the methods described and recommended will no doubt appear old-fashioned and out of date to the English or American bacteriologist; for instance, the directions given many years ago by Löffler for the preparation of nutrient broth are closely followed, as will be seen from this passage: "The faintly acid broth should be neutralised by the addition, drop by drop, of a concentrated solution of sodium carbonate, or better still made faintly alkaline"; while the author recommends the use of Unna's steam filter for the rapid filtration of agar. The ordinary methods of cultivation on plates and in tubes are well set out, but the useful "shake" culture is not even referred to. The section dealing with experiments on animals leaves much to be desired; the recommendation of Strohschein's syringe for inoculation purposes, for instance, will hardly meet with universal approval, while the directions for the immunisation of animals are practically valueless. In the illustrative example—that of the immunisation of the guinea-pig against cholera—the rule-of-thumb method given of inoculating the animal every eight or ten days is distinctly less efficacious and less scientific than that which regulates the intervals between the injections by the fluctuations of the "agglutination value" of the serum, but which is not even mentioned.

In the special portion of the book Enteric Fever is treated rather fully, considerable space being taken up by methods for the isolation of the bacillus typhosus, the most recent of these, that of Drigalski and Conradi, receiving due attention. In this connexion we note that in his description of the preparation of the nutrose-agar medium the author totally disregards the fact that in the filtration of agar a certain amount of the medium is invariably lost, so that the percentage composition of the finished medium as described by him varies considerably from that suggested by Drigalski and Conradi. Fig. 88, too, which represents the L-shaped glass rod employed in spreading the plates, shows the point turned up and rounded off in a manner that would effectually prevent the successful manipulation of the plates. Cholera is also fully dealt with but the other microbial diseases are dismissed very shortly. An appendix is included which contains directions for the bacteriological examination of water, air, soil, and milk. This is certainly the least satisfactory portion of the book, the methods quoted being antiquated and from the point of view of bacteriologists, in this country at least, totally inadequate. 12 plates at the end of the book display some 76 splendid photo-micrographs of pathogenic bacteria, malarial parasites, and anopheletes in various stages.

Hernia, its Etiology, Symptoms, and Treatment. By W. MCADAM ECCLES, M.S. Lond., F.R.C.S. Eng., Assistant Surgeon to St. Bartholomew's Hospital, &c. Second edition. London: Baillière, Tindall, and Cox. 1903. 7*s.* 6*d.* net.

THE average student of medicine knows comparatively little about trusses when he passes his final examination; he can, perhaps, distinguish between a truss for a femoral and one for an inguinal hernia, but to measure a patient accurately for a truss and to be sure that it fits, or if it does not fit to know what is wrong with it, would oftentimes prove too much for him. Though it is fairly easy to apply a truss to an ordinary case of hernia, yet much knowledge and skill are required when any unusual conditions are present. To all medical men who have to deal with such cases this little treatise by Mr. McAdam Eccles should prove very useful. It is elaborately illustrated with representations of herniæ and the forms of truss suited for them. All the chief operations for the radical cure of hernia are also described. An adequate account is given of all the varieties of hernia as well as of the treatment suitable for each. The work contains 100 illustrations, nearly all reproduced from photographs, and these certainly are very good. A very useful chapter is that dealing with Hernia in its Relation to Life Assurance, Accident Assurance, and the Public Services. On the whole, the author thinks that a hernia which is readily reducible and readily controlled by a truss should not constitute a reason for extra rating. Though in no way intended to be an exhaustive treatise on hernia, yet this volume supplies information much needed in practice and not readily obtainable elsewhere.

Die Krankheiten des Kehlkopfes und der Luftröhre, mit Einschluss der Laryngoskopie und Lokal Therapeutischen Technik, fur Praktische Aerzte und Studierende (Diseases of the Larynx and the Trachea, including Laryngoscopy and Local Therapeutic Technique, for Physicians and Students) By Dr. PHILIPP SCHECH, Professor at the University of Munich. Second thoroughly revised and enlarged edition. With 340 Plates and 89 Illustrations Leipsic and Vienna: Franz Deuticke. 1903. Price 7 marks.

Professor Schech's previous edition, which has been recognised as a standard work on laryngology, has been most thoroughly revised and the book now includes all the latest German work, though it will be noticed that but little reference is made to literature not written either by Germans or in the German language. The chapter on General Diagnosis and Therapy forms an excellent criterion for the rest of the work. It is not a compilation including all the remedies and methods of treatment at the disposal of the laryngologist but contains a careful description of all those of acknowledged merit. Every disease of the larynx is discussed and, where considered advisable, illustrations are added. The question of diagnosis between diseases difficult to distinguish one from the other, such as tubercle, syphilis, new growth and lupus, is entered into very carefully. If we are unable to say that there is very much that is new, we are merely stating generally the fact that, with the exception of some progress in the treatment of laryngeal tuberculosis and the research into the etiology of paralyses of the laryngeal nerves, especially the recurrent, the science of laryngology is to a certain extent stationary. The various theories of recurrent paralysis are considered and treated in a very lucid manner. As we have already intimated, Professor Schech's work occupies a high position amongst treatises on laryngology and will be found to be of great service both as a work of reference and as a guide for physicians and students.

Die Krankheiten der Oberen Luftwege. Zweiter Theil. *Die Krankheiten des Rachens. (Diseases of the Upper Air-Passages.* Second Part: *Diseases of the Naso-Pharynx.)* By Professor Dr. OTTOKAR CHIARI, Principal of the Clinic for Diseases of the Throat and Nose at the Imperial University at Vienna. With 118 Illustrations and 1 Plate. Leipsic and Vienna: Franz Deuticke. 1903. Pp. 260. Price 8 marks.

THE first two chapters of this part of Professor Chiari's work are devoted to the anatomy and physiology of the naso-pharynx. The next discusses the general pathology of this region in relation to interference with its functions, including interference with resonance, the effects of disease on articulation, interference with the ingestion of food in relation to diseases of the pharynx, and the neuroses of the palate, in what the author considers especially the globus hystericus, clonic spasm and ataxic affections of the palate, the remainder of the chapter being devoted to anomalies of secretion and of sensation, interference with the sense of taste, and vaso-motor diseases. Local treatment is described with the greatest attention to detail and is of an essentially practical character, the various remedies required and instruments used being dealt with at considerable length. The remainder of the work is chiefly confined to a discussion of the various diseases, their symptoms and pathology. The great knowledge that Professor Chiari has obtained from his long study of diseases of the upper air-passages makes the section of his work at present under consideration of the greatest value. He does not subdivide the affections of the faucial tonsil with the same minuteness as is customary amongst our French colleagues, but in contra-distinction to this those diseases of the naso-pharynx which do not accompany or follow the exanthemata, such as herpes, aphthæ, and other affections of the mucous membrane, as well as the various lichens and urticarias, are very fully considered, as are also the new growths and their treatment. The work is of the highest order throughout and being the outcome of long experience will prove of great value to all students who are especially interested in naso-pharyngeal surgery. The illustrations, although frequently reproduced from other works, are of the same high standard as the rest of the book.

The Five Nations. By RUDYARD KIPLING. London: Methuen and Co. 1903. Pp. 215. Price 6*s.*

A NEW volume by Mr. Kipling is always a source of pleasurable excitement to the reader who opens it for the first time and this collection contains some of his best work. Many of the poems show the writer's wonderful faculty for land- or sea-scape painting in words. Take, for instance, the poem "White Horses," or "The Sea and the Hills," or "Sussex," or, above all, "Bridge Guard in the Karroo," with its wonderful picture of sunset in a mountain-encircled desert.

"[illegible]

Royal the pageant closes,
 Lit by the last of the sun—
Opal and ash-of roses,
 Cinnamon, umber, and dun."

All who, like so many of our readers, have been in a like country will have it all brought back to them as they read. The poem which naturally appeals to us most from a medical point of view is the "Dirge of Dead Sisters" which is, indeed, a threnody worthy of its subject. Here are two stanzas:—

"[illegible]
 [illegible] …lowness,
 [illegible]

We are amused to think that Mr. Kipling is acquainted with the works of a remarkable poet who belonged to our own profession—namely, Dr. Thomas Holley Chivers, a passage from whose work, "Eonchs of Ruby" (this is not a misprint), is, surely, embodied in "Files." Not many medical men have been poets of any kind, but Chivers, although he wrote an infinity of verses which were all sound and no sense, occasionally produced a really fine line. But if he obtains immortality it will be from his having been referred to by Kipling and not on account of this sort of thing from "Virginalia":—

"More coy than the wild goldfinches
 When they hunt for the butterfly,
Which the dew of the morning quenches
 In the psychical month July,
Like an opaline dove's neck chiming
 Cherubic beauty for me
W[illegible]
[illegible]
O [illegible]"

Mr. Kipling's "Files" has a strong suggestion of Poe's "Bells," and the above quotation from Chivers shows that Poe derived models as well as amusement from the works of Chivers, which, indeed, he criticised in an essay that is extant. So that there is an hereditary sequence of events if Mr. Kipling has studied the works of Chivers, the unknown medical poet.

LIBRARY TABLE.

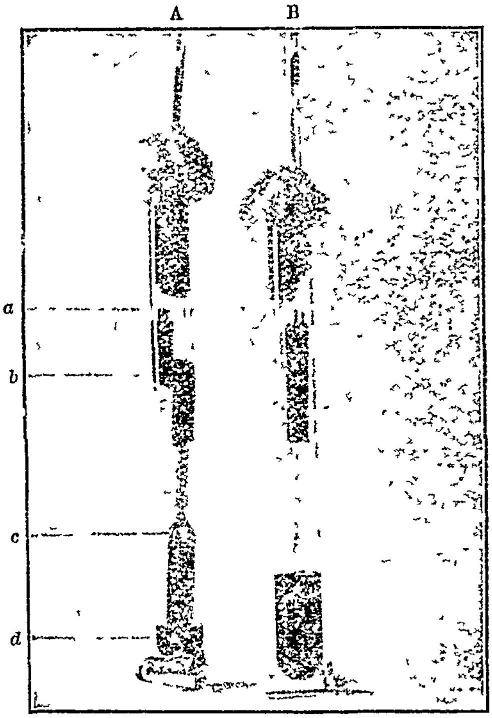
Literary Etiquette. By VICTOR G. PLARR, M.A. Oxon., Librarian of the Royal College of Surgeons of England. London: Adlard and Son. 1903.—Mr. Victor Plarr's little pamphlet says a great deal within the compass of its 15 pages. While stating that the old robust piracy of literary property is generally obsolete, he points out that in many matters literary ethics require improvement. In particular Mr. Plarr is interesting on the subject of literary ghosts. "If you employ a hack writer to make, say, a translation for you, come to an agreement with him on paper before he begins his work. ...... A man does not cease to have a literary reputation because you employ him. ...... Never trade upon your employé's modesty, or his belief in your integrity, or his unbusiness-like methods." Is the use of assistants, then, so wide-spread among authors as to require a code for its regulation? The unbusiness-like behaviour of editors comes in for the usual criticism and the one concrete example of editorial villainy requires a word or two of comment. "An editor," says Mr. Plarr, "has no *right* to order an article and then to return it unused after a long lapse of time accompanied by the customary printed formula of rejection." Granted; but how often is this behaviour dictated by kindness? The article is ordered and it is not exactly what is required; it is too long, it is too short, for half a dozen reasons it will not quite suit the needs of the paper. The simplest thing the editor can do is to send it back by return of post with a few words of rejection, explaining that although an article was ordered the one that has been received is of no use. But a kind-hearted editor thinks that perhaps, sooner or later, he may be able to use the article, or some of it, or may have time to revise it himself or to advise the author how to alter it. And so he keeps the article by him until a letter from the author, often a peremptory one—and we do not say that the peremptoriness is unjustifiable—demands from him an account of his stewardship. This is often the explanation of Mr. Plarr's story: these things are not always done out of naked wickedness.

A Handbook of the Diseases of the Eye and their Treatment. By HENRY R. SWANZY, F.R.C.S. Irel. Eighth edition, with Illustrations. London: H. K. Lewis. 1903. Pp. xx.+678. Post octavo. Price 12*s.* 6*d.*—This work is one of the best of the numerous manuals on ophthalmology that have appeared of late years and the numerous editions that have been published are sufficient evidence of the esteem in which it is held. The descriptions of disease are clear and good, the illustrations are excellent, and the paper and type are unexceptionable. The author has introduced many facts that have either been recently ascertained to be supported on good evidence or which serve to elucidate those which are generally accepted. Most of the additions are duly set forth in the preface; amongst the more important of these are a description of conjunctivitis petrificans and of various forms of keratitis to which special names have lately been applied, a description of the eye symptoms in myasthenia gravis, an account of P. M. Maxwell's operation for shrunken socket, and one of Professor Krönlein's temporary resection of the outer wall of the orbit for the removal of orbital tumours. Many of the chapters have been extended and the work has generally been brought well up to date. The sections on the diseases of, and operations on, the eyelids and upon the diseases of the lacrymal apparatus are particularly complete. For the relief of ptosis many operations have been devised. Mr. Swanzy describes Mules's, Pagenstecher's, Panas's, Everbusch's, and Hugo Wolff's methods, the account in each instance being accompanied by illustrations in the text which enable the steps of the operation readily to be understood.

New Inventions.

A TUBE FOR THE CULTIVATION OF ANAEROBIC ORGANISMS IN FLUID MEDIA.

IN the *Centralblatt für Bakteriologie*, vol. xxvii., p. 74, Professor J. H. Wright of Boston described a simple method of cultivating anaerobic organisms in glucose bouillon by means of an apparatus like that shown in the illustration. It consists of a piece of indiarubber tubing three inches long, uniting below with a glass bulb and above with an ordinary piece of glass tubing. The bouillon, after inoculation, is sucked up to just past the upper limit of the indiarubber, the upper glass tube is then pushed downwards with a little twist so as to cause a double angle in the indiarubber, and a column of liquid freed from the atmosphere is thus obtained for any anaerobic bacteria to grow in it. The present slight modification is in regard to the upper glass tubing, which is made longer and narrowed a little at one point so as to admit a small wool plug at the top. The whole test-tube can thus, after the usual sterilisation, be kept indefinitely, requiring only a short boiling and cooling just before use This method has answered admirably and besides the simple construction it has the advantage of doing away with the hydrogen apparatus, of showing any formation of gas in the inner column, and of differentiating a facultative from an obligatory anaerobe in the same specimen. Wright's ingenious plan seems to have escaped attention and my chief purpose in bringing this modification forward is to emphasise its simplicity and utility in growing anaerobic organisms in fluid media

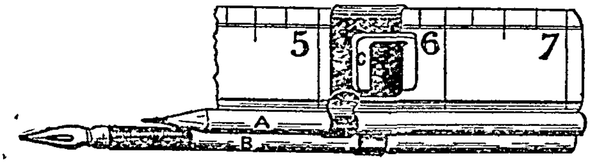


A, The tube after inoculation, and B, before use *a*, Upper limit of liquid *b*, Bend in the indiarubber *c*, Inner column, anaerobic. *d*, Outer column, aerobic

Gnoh Lean Tuck, M B , B C Cantab.,
Research Student, Emmanuel College, Cambridge.

A PEN AND PENCIL CLIP.

The accompanying illustration explains itself It depicts a main clip which embraces a graduated ruler and three smaller clips carrying respectively: (A) a pencil; (B) a penholder; and (C) a piece of indiarubber. The clip is the invention of Mr. J. Clark, F.R G S., headmaster of the Boys' Department of the Clay Cross Board School. The idea is that every boy will be able to keep separately for himself his own working utensils and so that a somewhat overlooked cause of infection will be avoided. It is, for example, not an unknown habit among board school boys—and for that matter among the boys of our famous public schools—to chew the end of the pen or pencil.



CLEANLINESS IN "GAS BAGS."

When during the course of the administration of nitrous oxide any "to-and-fro" breathing from the bag is allowed—and such a proceeding is often of advantage—it is obvious that a very thorough cleansing of the interior of the bag is essential if hygienic demands are to be properly observed. The most usual mode of obtaining cleanliness properly is to immerse the bag in hot water and to allow this to flow freely into the interior of the bag through the open vulcanite tap which is detached from the tube leading to the cylinders and, no doubt, the bag can be fairly cleaned in this manner after every administration. A much more efficient cleansing, however, is possible when the bag can be turned inside out. Mr. Vernon Knowles of Reading has contrived a bag of this description and in a recent issue[1] we gave an illustration of his apparatus. The process of turning the bag inside out takes certainly a little extra time, but this is more than compensated by the additional certainty of cleanliness, and the material of the bag is undamaged by boiling. Mr. Knowles's bag was first intended for use with ethyl chloride and similar anæsthetics, but since our notice of it in this capacity it has been adapted to the employment of nitrous oxide. The "reversible gas bags" may be obtained from the Dental Manufacturing Company in Lexington-street, London, W.

A WOOL TIDY.

This instrument consists of a serrated scraper or rake for the easy removal of cotton wool from probes, forceps, &c. It is firmly secured to the table by means of screws which pass through slots in the foot-plate but it is readily detachable. The wool is easily removed with one hand only by simply dragging the applicator firmly through one of the clefts with a slight rotatory movement, a difficult feat with the usual metal box which, owing to its unsteadiness, demands the use of both hands. It is made by Messrs. Mayer and Meltzer in two forms, with and without a well which is detachable for sterilising purposes Although specially designed for aural and nasal work it will be found equally serviceable in dental and other work which requires the use of wads for cleansing and escharotic treatment. When fixed the teeth should point away from the operator

THE LANCET.

LONDON: SATURDAY, OCTOBER 10, 1903.

The Opening of the Medical Schools: Introductory Addresses.

THIS year the introductory addresses at the opening of the winter session at the various medical schools, both metropolitan and provincial, were of more than usual interest, because they were less reminiscent of the medical pedagogy to which for so many years we have been accustomed. In certain instances the opportunity was taken to impart to the neophyte in medicine salutary admonitions on the necessity for a proper and Hippocratic appreciation of his future responsibilities, and this, we think, is a rightful use of the occasion on which introductory addresses are delivered. Similarly Sir DYCE DUCKWORTH's address to the students of the Medical Faculty of the University of Liverpool inculcated a very proper spirit. This address we published in full last week. As a whole, however, the addresses, apparently infected with the prevailing epidemic of Imperial expansion, took a more ambitious view of their objective and dealt with matters of national, if not of cosmopolitan, importance. Particularly so was this the case in the instance of the address delivered to the students of King's College Hospital by Sir JOHN A. COCKBURN and of the address delivered to the students of St. Mary's Hospital by Mr. V. WARREN LOW. Sir JOHN COCKBURN in an interesting manner pointed out the analogies between the development of empire and the organic evolution of individuals. Mr. LOW took as his subject the relationship of the military medical service to the civil profession and outlined a scheme for preventing the confusion, mismanagement, overlapping of duties, and general condition of unpreparedness which distinguished all departments of the medical service in the recent war in South Africa. The main principles which were advocated in Mr. LOW'S scheme were as follows: (1) organisation with the Royal Army Medical Corps as a framework; (2) for the medical reserve officer temporary rank equivalent to that of the regular service; (3) annual registration and payment while on duty; (4) graduation according to civil standing; and (5) appointments to definite army corps and if possible to definite units. The experiences of the late war brought to light many anomalies of administration and many personal grievances, especially in the relationship between the regulars and the volunteer civilians. The scheme which Mr. LOW'S personal experience in South Africa has enabled him to indicate deserves the consideration of the proper authorities. It is a clear, well-considered, and suggestive proposal for the organisation of a civilian medical reserve for the military medical services.

At the Yorkshire College, Leeds, Professor SCHÄFER, in eagerly pressing for reforms in our methods of education, touched upon another subject of the first Imperial importance. He congratulated the College on its newly granted charter and on its limitless opportunities for working out its own destiny on new and improved lines unhampered by the fetters of hide-bound traditions. He insisted on the superior advantages of practical work in the laboratories and of practical demonstration in the wards, as compared with the benefits to be derived from the attendance at lectures. The pertinence of this remark is self-evident when we realise that in these days of good text-books certain lectures have lost their *raison d'être* as instruments of education, a point upon which we recently enlarged in a leading article. Professor SCHÄFER strongly advocated the relegation of the study of most of the preliminary scientific subjects to that period of the educational curriculum which is antecedent to joining the medical school. We think that every year this becomes the more usual order of procedure and elementary chemistry, physics, and biology are now more often than not studied at school by those who intend eventually to take up the profession of medicine. A further suggestion on the part of the lecturer was that candidates for a medical diploma or degree should have at least the option of offering themselves for examination in the various subjects separately, as far as possible immediately after the courses in these several subjects were completed. This method, as opposed to that of grouping several subjects together, has probably as much to be said against it as for it—indeed, it lends encouragement to a system of cramming and superficial reading. If Professor SCHÄFER had the appointment of the examiners the plan might work, but the examiners who can distinguish between real knowledge and the appearance of knowledge that is lent by cramming are not numerous. As regards the sequence in which, according to Professor SCHÄFER, the various subjects should be taught in an up-to date and progressive medical school, such as that of the Yorkshire College aspires to be, we agree with his views; indeed, his scheme represents closely the method and order adopted in our metropolitan schools.

At the Charing Cross Hospital an interesting departure from conventional precedent was initiated by the invitation to Sir CHARLES WYNDHAM to deliver the opening address. The justification of this proceeding will be at once admitted by those who read the abbreviated report of his address which is reproduced in another part of our present issue. Although, to quote his own words, "his operations are now conducted in a theatre which is not strictly of a surgical character," nevertheless from a medical point of view, and by reason of the validity of his diplomas, there was nothing incongruous in this great actor divesting himself of his histrionic mask and addressing himself to a body of young students. Indeed, from his necessarily wide experience of worldly matters it is likely that his advice would carry at least as much weight in the estimation of his audience as would the words of any eminent physician or surgeon who, though occupying a high place in the medical profession, would probably possess a more limited and circumscribed knowledge of human affairs. Sir CHARLES WYNDHAM urged on his audience the necessity of showing moral courage in the conduct of their professional duties; "in this age," he added, "when the smaller vices are multiplying, each with its attendant nemesis of disease, have the courage to call things by their proper names; if a patient courts death or misery by drink, drugs, or vicious life, tell him so in the plainest terms. Do not disguise the truth by some euphemistic Greek phrase ending in 'itis.'" This advice is perfectly sound. There are cases known to all of us in which the patients may be intimidated into a fitting condition of submissiveness by the very verbosity of the high-sounding nomenclature which Sir CHARLES WYNDHAM deplores, but that is a small exception to the rule that plain speaking is generally the proper course. And plain speaking does not connote blunt rudeness and vulgarity. Our professional relationship with patients requires the exhibition of a quality—namely, tact—which can only be acquired by experience and by those only who have natural gifts for its acquisition. The example which Sir CHARLES WYNDHAM has set in making his introductory address an occasion for appealing to the humorous as well as to the serious instincts of his audience is one which is well worthy of being followed on similar occasions in the future.

◆

Accident or Disease? A Question in the Working of Compensation Acts.

THE Act dealing with compensation to workmen for accidental injuries suffered in the course of their employment, which came into force some five years ago, was calculated to be of considerable benefit to the labouring classes. This we allowed at the passing of the Act and an experience of its working since has confirmed this view. Certain trades and occupations have risks inseparable from the nature of the work which has to be undertaken and it is only just that the masters should be compelled to adopt every possible precaution for the safety of the men in their employ. A widespread system of insurance enables them to do so without imposing upon themselves, at any rate in most cases and with ordinary circumspection, an undue burden. But although the Act seems to have worked well hitherto there are not wanting indications that it is possible for the law to be subjected to serious attempts at abuse and if this be so amendment must be attempted. It is a curious fact that the classes in which are included operatives and labourers are prone to misuse the laws made for their benefit. They love to apply these to purposes for which they were never intended. Trade unions are a striking example of this statement. Originally they were regarded as illegal combinations, but they obtained legal recognition on the understanding that they were necessary to prevent tyranny on the part of the employers of labour. It is certain that they have done this and have led to the amelioration in many respects of the conditions under which certain trades are carried on, but the trade unions have on occasions been perverted to obstructive tactics with the most pernicious effects on the commerce of the country. The details of the Taff Vale case sufficiently prove the mischief that may be done by a trade union working improperly.

The peril which menaces the benefits conferred by the Workmen's Compensation Act has not yet made much appearance in England but two instances of possible abuse under similar legislation in France have been recently referred to by our Paris correspondent.[1] In both cases an attempt was made to include improperly under the term "accident" an illness or disease contracted by a workman during his employment. In the first instance a worker in a glass factory contracted syphilis through using a blow-pipe which it was alleged had been infected by one of his fellow labourers. He thereupon demanded damages from his employers and brought the matter before the courts. The judge nonsuited the plaintiff on the ground that he had adduced no proof that syphilis had been contracted in the manner alleged, while a further proof of the weakness of the case lay in the fact that his fellow workman was examined medically and showed no trace of syphilis. In the second case a railway porter referred a pulmonary hæmorrhage to the strain of lifting a trunk which was too heavy for him. At the time of the so-called accident he presented no signs of pulmonary tuberculosis but the disease manifested itself within a short period and he accordingly, with the advice of his medical attendant, sued the railway company for damages. The railway company, dreading a case against it which might in the future be used as a precedent, preferred to compromise the matter by paying the plaintiff a sum of money. It seems to us a matter of regret that this course of action was adopted, as it lays the railway company and similar bodies open to claims of this sort in the future, a development which would lead to action on the part of employers of labour of a sort which could not fail to be irksome to the employed classes. Labour agitators would, we think, have no difficulty in inducing the employed to believe that such actions at law as those to which we have alluded are for their benefit. We trust, however, that no attempts in this direction will be made, as disastrous results would be likely to follow. If the workman who claimed compensation from his employers because he had contracted syphilis from a fellow workman had proved successful in his case the employers would have been perfectly justified in discharging every man on their wage-roll who showed signs of syphilis. And as the individual infected with syphilis will often, and naturally, deny ever having had the disease a further step might be expected—namely, refusal of employment to any man having a cutaneous eruption in case it should be of a syphilitic nature. With respect to tuberculosis a similar course of action would be justified if such a symptom as pulmonary hæmorrhage were held to be an accident within the meaning of the Workmen's Compensation Act. Not only would the unfortunate victims of the disease suffer by being discharged from their work but any man or woman who developed a cough would run the risk of dismissal on the plea that "consumption might be developing."

We need not enter into the many questions which have arisen in respect of the measure of the infectivity of tuberculosis; suffice it to say that if due precautions are taken the risk of infection is reduced to a very small one. If an employé is known to be tuberculous it is the duty of the employer to see, as far as possible, that all means are adopted to prevent the sufferer from becoming a danger to his fellows. Instructions should be given both to him and to them and then if the injunctions are persistently or wilfully neglected dismissal of the disobedient would be justified. But an employer is not necessarily supposed to be aware whether those under him are afflicted with syphilis, tuberculosis, or any other constitutional complaint. The symptoms of these diseases and of others which to some extent are communicable by man to man are varied and uncertain, and it would be unjust without careful inquiry into the master's knowledge of the state of affairs that he should be mulcted in damages because one workman might infect another. The Workmen's Compensation Act did not contemplate such a position and no such intercommunication of disease can be regarded as an accident for which compensation is due. It is suggested by our Paris correspondent that lead workers and the employed in similar trades intend to try the question legally whether poisoning as the results of their work can be considered as an "accident" compensation for which must be paid by the masters. We have every sympathy with workers in dangerous trades who fairly expect, and ought to receive, a high rate of remuneration, but to mix up disease with accident as concomitants of labour must lead to confusion and to injustice. The private life of the workman may predispose him to the malignant effects of the poison of syphilis or alcoholism, but if a breakdown in health should occur in such individuals it cannot be regarded as an accident. Still less can a mischance to one of their fellow workmen arising out of a fellow workman's condition be regarded as an accident for which the employer must pay compensation. Where would such a state of things end if once such a theory of "accident" were admitted? Defective social surroundings, speaking in the most general terms, undoubtedly constitute a danger to the health of the workman and may conduce to his breakdown while he is a wage-earner, but such occurrences, though very tragic, cannot be laid at the door of the masters. Certain *risks* must be taken in all classes of life and it would be equally foolish for a medical practitioner to claim damages from a patient from whom he had contracted an infectious disease, such as scarlet fever, as it would be for a workman in lead or phosphorus to consider lead or phosphorus poisoning as an "accident." The risk of the employment must be considered in the wages and the employés must be made to minimise these risks as much as possible, but the Workmen's Compensation Act was meant to meet cases of genuine accidents.

---

[1] THE LANCET, Sept. 19th, 1903, p. 854.

Quackery and Death.

THE Manchester city coroner, Mr. E. A. GIBSON, recently concluded an inquest in which he investigated with commendable thoroughness the causes responsible for the death of a child. The outline of the facts which were brought to light may be given in very few words, as the story is referred to in detail by our Manchester Correspondent this week. The deceased was taken ill, or was observed by the parents to be ill, on a Saturday. No medical practitioner was summoned but a quack medicine called "Jackson's febrifuge" was administered by the father, because, as he said, it was well known and the neighbours advised him to try it. The child died on the following Monday and the coroner's jury found a verdict of "Death from natural causes." This was strictly correct, for medical evidence showed that the cause of death was broncho-pneumonia and death probably was not accelerated, as certainly it was not retarded, by the use of "Jackson's febrifuge." There is a delicate irony perhaps in recording as a death from "natural" causes the decease of a child left to die with no other assistance in the struggle for life than nature might afford, but there was no evidence which could render JACKSON directly responsible for the tragedy.

We quite recognise that there must be considerable difficulty in bringing home in these cases, which with trifling differences of detail are so common, the grave charge of manslaughter either against the quack medicine vendor, or against the parent who uses fraudulent concoctions upon his luckless children instead of asking the advice of a medical man. In some cases where medical aid is not summoned, the charge of neglecting to procure it, resulting as it does in causing a child unnecessary suffering, may secure the conviction and punishment of the parent, but these prosecutions, as a rule, take place in somewhat different circumstances. Our Manchester Correspondent also reports this week that a father, residing at Manchester, was recently sentenced to imprisonment because, being a disciple of the man DOWIE, he had recourse to prayer, and prayer only, on behalf of his child who was suffering from a broken collar-bone It can be contended that there is a difference between relying upon a quack's "febrifuge" recommended by a neighbour in a case of pneumonia and trusting to prayer and Providence when a collar-bone is found protruding through the skin. But the distinction is a theoretical rather than a practical one. In each case the child would suffer needless pain. The disciple of DOWIE may appear to most people to have treated his child with the greater callousness as the administrator of the quack potion can contend that in selecting JACKSON and his "febrifuge" he had exercised his right to choose his own medical adviser. Mr. ESTCOURT, the analyst of the city of Manchester, said in his evidence that he had made an analysis of the "febrifuge," and the following were the constituents, with their approximate quantities: chloride of ammonium, 4·0 grains per fluid ounce; chloride of potassium, 2·4; sulphate of potassium, 6·2; sulphate of sodium, 4·0; sugar, 10·4; ipecacuanha, (nearly) 2 0; camphor, (nearly) 1·0; cloves, ginger, liquorice, and probably rhubarb, 9·0; and chloroform, faint trace. The witness further said that the bottle he received in order to make his analysis contained four ounces and that the mixture was of such a complex nature as to render it impossible to estimate accurately the small quantities of some of the constituents present. He found no trace of any poisonous substance save chloroform in the medicine. A statement was made to the coroner by a solicitor representing the compounder of the "febrifuge" to the effect that it contained 14 active ingredients and three inactive. It was suggested that the chloroform would act as a preservative from decomposition and that it was there for that purpose only. The general correctness of the analysis was in no way disputed but JACKSON himself, before the adjournment for the purpose of analysis was made, had refused to say anything as to its composition beyond describing it as a herbal remedy. A pamphlet was produced in evidence which claimed for the concoction above described that it would cure about 30 specified diseases, including consumption, rheumatism, quinsy, and chicken-pox, or, as the coroner expressed it, "everything on the face of the earth." JACKSON went into the witness-box and showed himself there no less audacious than in his pamphlet. He boasted of selling thousands of gallons yearly, bandied words with the coroner who without mincing matters described the traffic in the "febrifuge" as a common swindle, and alluded to having given death certificates in 150 instances. Can it be a fact that registrars have accepted this man's official notifications of deaths and in such numbers? JACKSON'S qualification for carrying ont he business of a druggist consisted, according to his own evidence, in his having done so before the passing of the Pharmacy Act Amendment Act of 1868. He has therefore had a long career and no doubt a profitable one. Reference has been made to a sale of thousands of gallons; the precise figure given by JACKSON'S advocate showed that it amounted to 87,360 shilling bottles (2184 gallons) during last year.

In considering whether it is right that a traffic of this kind should go on unchecked it should be borne in mind that in the case under consideration the child died and that under medical treatment in all probability the child would have recovered. At all events the chance of recovery would have been afforded. Two questions further may be asked. Ought a parent to be able with impunity to allow his child needlessly to die simply because he administers somebody's cure-all pill or potion? And, secondly, Ought the pill or potion to be sold with impunity to ignorant people by means of pretences with regard to its powers which are provably false? The Manchester city coroner appears to have told the jury candidly with regard to JACKSON that he was an absolutely ignorant man and a quack and that it was perfectly scandalous that he should be allowed to do a business of the kind which he undoubtedly does. His words would refer equally to scores of persons who carry on a like traffic with like impunity, and the coroners who use plain language about such a condition of things do real good to the community.

Annotations.

"Ne quid nimis."

THE RECONSTRUCTED CABINET AND PUBLIC HEALTH.

THE changes which have recently taken place in the Cabinet have not obviously affected the position as regards public health administration, but the fact that Mr. Walter Long is apparently to remain at the Local Government Board is not without significance. The place at present occupied by the Local Government Board, which Sir Michael Foster has termed "the hierarchy of Government departments," is not such as to justify the indefinite retention of a Minister of Mr. Long's ability and record as its Parliamentary head, and were there not important changes in store for that department it might reasonably have been expected that Mr. Long would have been transported to one of those nominally more important posts which carry with them not only a substantially greater emolument but also the coveted title of Secretary of State. The fact that no such promotion has been made lends colour to the belief that the special committee which has been appointed to inquire into the working of certain Government departments, of which the Local Government Board is one, may see its way to recommend that the time has now arrived when the enormous expansion of local government throughout the country calls for a corresponding development in the central health department and for some strengthening of the position which its Parliamentary head occupies in the Cabinet. There are some who think that this development should take the shape of the creation of a Minister of Public Health, but we doubt if those who advocate this have a very clear conception of what is meant by this term or of the difficulties which beset its accomplishment. Public health is a part and parcel of our present system of local government and the first step to take is so to enhance the central department of that great system as to afford it a better chance of being adequately represented in the Cabinet. In our view this step will be likely to make for greater efficiency in the public health administration of this country than would the appointment of an isolated Minister of Health who would preside over a department which would be the youngest in the State and the representative of which, *if any*, in the Cabinet would occupy a relatively inferior position. Moreover, there is at present practically no prospect of the appointment of a Minister of Health with a seat in the Cabinet. If an *addition* is made to the Cabinet it will probably take the shape of a Minister of Commerce. But there is, we believe, a fair prospect of the elevation of the central health department to the dignity of a Secretaryship of State and every effort should be made by local governing bodies throughout the country, quite irrespectively of any political bias, to see that the status of the cause for which they labour is properly represented in the Cabinet. But we are far from contending that the medical department of the Local Government Board can be regarded as receiving at the present time the support or status which must be accorded to it if it is to continue to lead the public health administration of this country. In our view it should undergo very material expansion. It is a somewhat strange anomaly that the medical officership of the Local Government Board, a post which carries with it the duty of advising other Government departments in a manner which intimately concerns the development of preventive measures in the empire as a whole, should be accorded a remuneration smaller than that which is given to the medical officers of the Royal Navy or the Army Medical Department. It is strange, too, that the grant of £2000 per annum for scientific investigation which was, we believe, accorded to the central health department at a date prior to the passing of the Public Health Act of 1875 should still be regarded as adequate. No wonder that in these circumstances the research work done in Germany in matters relating to the public health has of recent years far outstripped the progress made in this country. If the State sets an example such as this it is somewhat difficult to find fault with the tardiness of local administrative bodies. Possibly the Treasury in failing to afford the Local Government Board a more adequate financial support has in mind the fate which in the year 1854 befell the little band of sanitary reformers which was led by the late Sir Edwin Chadwick. Possibly, too, that memory might still militate against the creation of a Ministry of Public Health. But circumstances have altered since Sir Edwin Chadwick's time and now in every sanitary area throughout the country there are at least some representatives of local government who would welcome a more vigorous central administrative action. If, therefore, the time is not yet ripe for a Ministry of Public Health there is at least need for some expansion of the public health services and a general coordination of its several branches

THE PISTOLS ACT

THE first case that has come before a magistrate under the Pistols Act, 1903, was heard by Mr Curtis Bennett recently as the result of a young man accidentally shooting a tobacconist who was serving him It was found by the police that the pistol used upon this occasion had been lent to the person carrying it by the owner, a youth under 18 years of age, and that he had bought it from a man trading in the Edgware road, who had committed two offences under the new Act—in selling without observing the formalities prescribed by the new Act and also in selling at all to a youth under 18 years of age The seller of the pistol pleaded complete ignorance of the Act which only came into force on August 11th very shortly before the sale in question took place He was accordingly bound over to come up for judgment when called upon under the first summons and under the second was fined 5s with 2s costs The youth who bought the pistol was also summoned and bound over and the person who was carrying it without a licence and whose careless handling of it had injured the tobacconist was fined These two, also, were ignorant of the provisions of the law In the columns of THE LANCET we have very frequently called attention to the serious danger to life and limb arising from the unrestricted sale of cheap firearms to irresponsible, ignorant, or ill intentioned people and it is satisfactory to note that in an instance such as this two out of the three persons involved could be dealt with under the Act which has recently come into force and that the third, owing to the attention called to his conduct, was punished under the previously existing law The Pistols Act of 1903 has been considerably improved since its first appearance in the shape of a Bill and though it may easily become inoperative if there is any want of system and care in enforcing it, it is quite capable of achieving the results at which its promoters have aimed and of putting an end to a very dangerous trade The Act makes it unlawful to sell or to let a pistol to anyone not producing a gun or game licence, unless he be entitled to carry a gun without having such licence or being a householder intends only to use the weapon in his house or curtilage, or is a person who requires it for use abroad. Every person selling or letting a pistol is to enter the transaction in a book with full particulars of the weapon, of the name and address of the purchaser or hirer, and of the gun or game licence produced by him, and this book is to be open to the inspection of any police officer or officer of Inland Revenue No one under the age of 18 years, except those exempt from penalties for carrying a gun without a licence, is to be allowed to buy, to hire, to use or to carry a pistol and any such person may be ordered by a magistrate to forfeit any pistol found in his possession Fines ranging up to £5 may be imposed for the infringement of these provisions but for knowingly selling to a person intoxicated or not of sound mind a penalty of £25 may be inflicted or a term of imprisonment with hard labour not exceeding three months The Act does not apply to Ireland It will be seen from this summary that should the police and the Inland Revenue but particularly the former, exercise vigilance in the matter the selling of revolvers as cheap toys in shops and the promiscuous brandishing of them by boys in the streets should entirely cease The love lorn youth with ill balanced mind who has hitherto experienced no difficulty in shooting his sweetheart and then himself should also find time for reflection during the preliminaries necessary to the fulfilment of his purpose, even if the difficulties put in his way do not altogether prevent him from carrying it out The more sane and deliberate criminal may not be affected but the use of the pistol by criminals may be said in general to vary in inverse proportion to their sanity It is to those reckless of the penalty attaching to murder that it has generally proved attractive It may be suggested that the police should take steps throughout the country in order that no one dealing in cheap pistols should be able to plead ignorance of the law It is not a plea that will excuse him but it may be taken into account by the bench which tries him The official printers, who in London are Messrs Eyre and Spottiswoode, East Harding street, E.C , sell the Act at 4d a copy, so that even the hooligan of less than 18 years of age may easily possess a copy should he desire to do so

NEED SMOKE BE "BLACK" TO CONSTITUTE AN OFFENCE?

IN the report of the medical officer of health of the City of London for the nine weeks ending on Sept 12th, 1903 we are glad to note that the authorities are keeping an active watch over those who have no regard for the purity of the air and its freedom from filthy smoke A list of offenders is given and the medical officer has recommended that notices should be served upon the owners or occupiers of the premises named to abate the nuisance and to do what is necessary for preventing a recurrence of the evil, "failing which Mr Solicitor be instructed to take such proceedings as he may consider necessary to enforce your (i e , the sanitary committee's) orders " In ten other cases in which the names and addresses are also given the evidence obtained is at present insufficient to warrant active interference Whilst we admit that a good deal has been done towards suppressing the smoke nuisance, yet there is still, we think, plenty of opportunity for other authorities to instruct "Mr Solicitor to take proceedings" elsewhere According to our observations the offenders are chiefly occupiers of restaurants and dining-rooms It is regrettable, we think, that in Section 24 (b) in the Public Health (London) Act the word "black" as applied to offensive smoke is retained There is abundance of smoke given off by chimneys in London which is not black yet which is an intolerable nuisance As Dr W. Collingridge says "Many complaints are received of smoke nuisances which we are unable at present to deal with by reason of the fact that the smoke emitted—although intolerably objectionable—is not black, but of some less pronounced tint as yellow or brown On occasions we get complaints of nuisance from even white smoke " We may add that we have experienced a blue smoke that was very objectionable We heartily agree therefore with the Westminster City Council and the Corporation of London that the word "black" should be deleted from that section of the Public Health Act dealing with the smoke nuisance

ADDITIONAL OBSERVATIONS UPON TENT LIFE FOR THE TUBERCULOUS INSANE

SINCE the last report on tent life for the tuberculous insane by Dr A E Macdonald, medical superintendent of the Manhattan State Hospital for the Insane, a matter which was dealt with in a leading article in THE LANCET of May 2nd last, p 1249 a further report has been issued on the subject by Dr A B Wright and Dr C Floyd Haviland, both resident assistant physicians of the asylum The report deals with new developments and recent departures in regard to the treatment of the patients The camp for tuberculous patients has been enlarged and a separate tent has been provided for the accommodation of the more active patients and those suffering from mixed infections In general the isolation of the tuberculous patients has been made more complete as in no circumstances are they permitted to mingle with non tuberculous patients This enforced isolation is bearing fruit in the lessened number of cases diagnosed in the wards of the hospital. Encouraged by previous success it was determined to carry on the camp in its entirety during the winter 1902-03 and the same successful results have characterised this effort as marked the camp treatment during the summer months. In addition to the two large tents used previously a third large tent was erected on the present occasion. This contained no beds but was partitioned by screens into a dining room and a living room for such patients as were not confined to bed. For it was found that only the large tents could successfully withstand the severe weather of the winter months and by this new arrangement it was possible to dispense with the small auxiliary tents. Large coal stoves provided ample heating facilities in severe weather but a high indoor temperature was avoided inasmuch as the cool air had, in this treatment, appeared to exert a decided therapeutic effect of its own. The large living tent was left somewhat cooler than the other tents, so that patients in going in and out of doors passed through it and avoided too sudden changes of temperature. Notwithstanding the constant exposure "not a case of ordinary cold or pneumonia developed during the entire winter" and even when the climatic conditions were unfavourable the patients could securely live a constant outdoor life. A high dry altitude was demonstrated to be essential for the successful treatment of pulmonary tuberculosis. The mortality rate of tuberculous patients during the winter 1902–03 was found to be appreciably lower than that of the previous year. Of 61 patients with slight or moderate tuberculous disease 53 gained weight, seven lost weight, and one remained unchanged. The average gain of weight was 15½ pounds per patient. The general principles of treatment and diet were carried out as in the previous season. The statistics, add Dr. Wright and Dr. Haviland, show a decided improvement over those of the preceding year and encourage the further continuance of the methods of treatment adopted.

THE M.D. DEGREE OF BRUSSELS.

On p. 1037 we publish a communication from Dr. N. Leonard who states very clearly the procedure necessary to obtain the M.D. degree of Brussels and estimates fairly the difficulty of obtaining the degree and the standard of scientific attainment required to cope satisfactorily with the examinations. He concludes his remarks, which will be of value to some of our readers, by saying that the time and trouble spent in the attainment of the degree will be amply repaid in an improvement of social status, and we think that he is right. We also think it particularly unsatisfactory that he should be right, for surely it is an absurd position that the medical man of a country like ours should find it necessary to go to Belgium for a professional hall-mark. We are not intending to open up an endless discussion upon the use of the title of "Doctor." Everyone knows that the title is used in two ways—academically when it implies the medical degree of a recognised university and colloquially when it implies the carrying on of the profession of healing. Everyone also knows that in professional opinion it is wrong for the medical man who does not possess a medical degree to style himself "Doctor," but a practitioner cannot help the fact that his patients will habitually style him "Doctor." The double use of the title has produced an ever-annoying situation. Undoubtedly it is a disadvantage in medical practice that it should be possible to say of any man that he has no right to the title of "Doctor." The public do not understand that only non-possession of a certain university degree is implied, not an inferiority of some sort or other as a practitioner. This mental confusion of the public is particularly hard upon a large number of medical practitioners who hold excellent diplomas, because the work that they have done for these diplomas would as easily as possible have obtained for them a university degree had circumstances placed a university curriculum before them. The holder of the diplomas of the English Conjoint Board has passed tests as stringent as those required for medical degrees in many of the universities and the only reason why such a practitioner does not possess a medical degree is that he was educated in London. He has had the advantage of attending some famous metropolitan school and of seeing clinical practice in an institution where the wealth of material is unrivalled but not being prepared to give up the time necessary for the obtaining of the M.D. degree of the University of London he is without the title of "Doctor." Dr. Leonard recommends that in this plight he should have recourse to Brussels and in the present position of affairs doubtless there are many who will follow his advice. But we may hope that the reconstituted University of London will soon be able to offer to the London student a proper opportunity of obtaining a medical degree. Already the matriculation examination of the University is a fairer introduction to graduation than it used to be and we look forward to the time when a simplification of examination processes, which is not the same thing as a lowering of scientific standards, will lead more London students to try for the medical degree of their own university.

THE KING'S SANATORIUM.

In *The Health Resort* for October appears a paper entitled "The King's Sanatorium. A Waste of Lives and Money. A Criticism by Chas. Reinhardt, M.D." After a careful perusal of this article we can only express our regret that it has ever appeared in print. It is founded on views which we feel sure will not be supported by the majority of those who have had extended experience in the sanatorium treatment of pulmonary tuberculosis. The very title of the communication is objectionable and its publication may be productive of harm and much misconception with regard to a most excellent and carefully considered scheme. There are many sentences in Dr. Reinhardt's paper to which we take strong exception, but space forbids us from mentioning them all. Dr. Reinhardt starts with the assumption that a "costly, substantial, and not altogether appropriate hospital of 'palatial' character" is to be built. Considering that the plans have not yet been made public we entirely fail to understand how Dr. Reinhardt is aware of the detailed nature of the building which is to be erected; consequently the oft-repeated word "palatial" is meaningless. It would have been in much better taste if such an epithet had been withheld until the plans were known. We feel, moreover, that nothing could be further from the committee's wishes than that a "palace" of any kind should be constructed. Dr. Reinhardt's main contention is that the sanatorium should be built on the chalet, instead of on the pavilion, system. He says: "Every physician who has had the opportunity of comparing the results of treatment upon the chalet and room principles will accept the following statement: Incipient cases are cured in 25 per cent. less time where chalet patients are concerned than is the case where patients occupy rooms." We feel sure that such a statement is not correct and we have derived our information from those who have had practical experience. It is possible that in a suitable climate the chalet or hut system is preferable when only a few patients, say up to 20, have to be dealt with. Above this number, however, the difficulties in administration and nursing are so great that the advantages of the huts are far over-shadowed by the discomforts inseparable from a large number of chalets scattered over a considerable area of ground, at any rate in this country. Dr. Reinhardt attempts to prove that, owing to the King's advisers not having adopted the chalet system, by the time that the "Haslemere Palace" will be ready 7800 persons might have been saved from suffering and their lives prolonged. The method of arriving at these figures is singular. Instead of erecting a sanatorium for 100 patients as is proposed he maintains that ten sanatoriums, each capable of holding 100 patients, could have been built in different parts of the country for the same sum as that which it is proposed to spend on a single sanatorium. We greatly doubt whether these figures will bear investigation, considering that the cost of the sites, water-supplies, and building of these ten separate institutions is included. We trust that we have said sufficient to indicate the unpractical and unscientific nature of Dr. Reinhardt's paper and to counteract the very false impressions to which it may give rise.

CEREBELLAR TUMOURS AND THEIR TREATMENT BY OPERATION.

IN a recent annotation[1] on the subject of brain surgery it was stated, on the authority of cases collected and observations made by Professor M. Allen Starr, that tumours of the cerebellum were rarely accessible to surgical operation. In the *American Journal of the Medical Sciences* for September Dr. W. H. Hudson records two cases of operation for cerebellar tumour, in both of which the tumours were found in the right lobe of the cerebellum and recovery followed operation, though one patient died unexpectedly from an intercurrent disease. The first case was that of a girl, aged nine and a half years, who in the summer of 1895 developed headache, vertigo, and attacks of vomiting, and from being a bright and lively girl became inactive and disposed to be in bed. After some time there followed symptoms of staggering gait and failing eyesight and the diagnosis of cerebral tumour was made. The pupils were widely dilated and did not react to light. There was paresis of the right facial nerve. The muscles of the neck were stiffened and the head was slightly retracted. The mother of the patient stated that when the child awoke in the morning "her head was drawn far back and that it took several hours of hot applications and rubbing before she could straighten her neck." Pain was elicited by firm pressure over the right cerebellar fossa, both knee-jerks were absent, the grasp of the left hand was much weaker than that of the right, and the left leg was also weaker than its fellow. The patient could not walk without assistance and if unsupported would stagger and fall towards her left. Ophthalmoscopic examination showed intense neuritis in both eyes. She eventually grew more feeble and emaciated and it was decided that an operation should be undertaken. This was performed on June 15th, 1896. On opening the skull in the region of the right lobe of the cerebellum the dura mater bulged out tensely "like a well-inflated bicycle tyre." On opening it a tumour was discovered superficially forming a mass "half as large as an English walnut," and this was excised together with a small portion of brain substance which protruded around it. The basal part of the tumour was thought to have infiltrated the brain substance and as much of it was removed as seemed proper. The patient recovered from the operation, she grew cheerful and happy, but weakness and incoördination of movement still persisted. A hernia cerebri gradually developed after the operation and attained the size of half an apple. A second operation was decided on as signs of a cystic accumulation of fluid (or blood) in the brain manifested themselves. At this operation a hæmorrhagic cyst was found and evacuated, its location being deep within the right cerebellar lobe. The cyst had been growing unsuspected at first and had destroyed most of the right lobe and adjacent parts of the cerebellum. She made an uneventful recovery after this and four months later was enjoying excellent health. She now walked well, showing very few defects of coördination, and eight months later was shown at a medical meeting at which time she was still in a good condition of health. The optic neuritis had, however, gone on to optic atrophy some time previously and she was now quite blind. The second case was that of a man, aged 29 years, an athlete. At 12 years of age he had been struck by a stone from a sling above and just behind the right ear. The scalp was cut to the bone but at the time the bone was considered uninjured and nothing further was thought about the accident. A few years later he began to suffer from headaches and also from "a peculiar feeling in the [right side of the] head but this feeling was not described as pain." He developed diplopia and a staggering gait and began to suffer from attacks of vomiting. Failure of vision gradually followed and epileptiform attacks supervened. A striking symptom in such attacks was the turning of the entire body, especially the head and shoulders, to the right (screwing movement). He was unable to stand up or to walk. The mental condition was normal. The symptoms, which also included double optic neuritis, tenderness to pressure over the right occipital lobe, and paralysis of the right external rectus muscle and seventh nerve, indicated that there was a growth in the right cerebellar lobe. An operation was performed and on opening the skull and cutting open the tense dura mater *a deep-seated tumour was found by palpation. It was* estimated to be three-fourths of an inch below the surface of the brain and of solid consistence. The tumour was removed by enucleation with the finger and was of about the size of a hen's egg. Practically the entire right lobe of the cerebellum had been destroyed by the growth. The patient rallied after a period of temporary collapse of respiration. On the third day after the operation he appeared to be in a remarkably good condition, his headache was gone, his eyesight was improving, and the wound was healing without hernia cerebri. Shortly afterwards, however, while continuing to improve as regards his cerebral symptoms, he contracted a severe form of diarrhœa with vomiting from which he died on the eleventh day after operation. The tumour was found to be a tuberculous one. Dr. Hudson points out that in both cases the tumours were well placed for surgical operation and advises that this should be resorted to in cases of cerebellar tumour, since a fatal issue is otherwise inevitable.

SEA WATER FOR STREET WATERING.

SOME years ago the municipal authorities at Hastings tried the experiment of employing sea water for watering the streets and flushing the sewers and their example was soon followed by the local authorities of a number of other towns on the coast. The wastefulness, not to say folly, of using for such purposes water that had at considerable labour and expense been filtered to the highest attainable degree of purity seemed obvious and though, of course, it involved the installation of a separate system of pumping station, mains, and hydrants, the fact that the supply was inexhaustible and itself cost absolutely nothing was so evident that it was strange that this source had been neglected so long. The sanitary and economic results seemed more than to justify the innovation, for, to say nothing of its slightly antiseptic action, the hygroscopic property of the salt caused the effects of each watering to last for a much longer time, and the surface of the roadway was believed by some to be more compact and cohesive, than when fresh water was employed. Besides these retrenchments the new system presented a direct source of revenue in the demand by many private householders for a salt-water service to their bath-rooms so that they might enjoy the luxury of sea bathing at home. But a few years' experience has unfortunately brought about no small disillusionment; the owners of carriages complain of the destructive action of the salt mud on the varnish and paint and the tradesmen complain of the injury inflicted on goods of all kinds by the salt dust and its subsequent deliquescence. Lastly, the users themselves, the local authorities and their private customers, have discovered that the salt water exerts such a corrosive and generally destructive action on metal pipes and fittings that the number of persons contracting for a domestic supply has fallen from 200 to two and the leakage from the joints of the street mains has caused the deaths of the trees planted in the best streets and promenades, so that the engineer to the corporation that had been the pioneer in the movement finds himself compelled, in an exhaustive report of its experience, to admit that the system has proved a complete failure.

---

[1] THE LANCET, August 15th, 1903, p. 485

HORSE DUNG IN THE STREETS.

THE prompt removal of horse dung is of the greatest service in promoting the cleanliness of the streets, but not even the most diligent scavenging can protect the surface of the roadway from a certain amount of fouling. Dr. J. A. Calantarients of Scarborough thinks that the difficulty may be solved by catching the droppings before they fall to the ground and for this purpose he has devised a collecting shoot and receiver to be attached beneath the front of the vehicle to which the horse is harnessed. This contrivance is minutely described by him at p. 1050 of our present issue and his opinion that it is not very obtrusive or ugly is fully borne out by a photograph which he has sent to us, showing an open four-wheeled carriage fitted up as he suggests and with a horse in the shafts. If in practice it carries out all that is claimed for it and horse-owners could be induced to make use of it the expense of scavenging no doubt would be greatly reduced and the public would be benefited in many ways.

SUBPARIETAL INJURIES OF THE KIDNEY.

THE *Boston Medical and Surgical Journal* of July 9th and 16th contains an important paper on Subparietal Injuries of the Kidney, by Dr. Francis S. Watson. It is based upon six cases observed by him and on 660 previously published cases. Laceration or serious injury of the kidney may be produced by muscular action and sometimes by apparently inadequate force. For example, a man sprang backwards and felt a violent pain in the left renal region. At the first micturition afterwards hæmaturia appeared and it persisted for four days. A perinephritic abscess followed. In another case a man in lifting a woman across a bed felt severe pain in the loin. Hæmaturia followed and persisted for three weeks. In a third case a man ruptured his kidney with fatal result in the muscular effort of delivering a blow in boxing. 20 cases have been recorded of laceration of the kidney from blows on the front of the abdomen. Abdominal symptoms may appear immediately after the injury or as late as the second day. Tumour of the loin was observed in 111 out of 486 uncomplicated cases. In 39 of them the tumour was due to a perirenal extravasation of blood, in four to hæmatonephrosis, in 28 to hydronephrosis, in 38 to perinephritic abscess, and in two to pyonephrosis. According to Küster laceration of the kidney after non-penetrating wounds is explained by hydraulic pressure acting through the full vessels and pelvis and causing the organ to burst along lines radiating for the most part from the hilum towards the point of maximum impact of the lower ribs. In one case Dr. Watson sutured the renal wound, an operation which appears to have been performed previously in only six cases. The patient was a man who fell on his back while stepping off his cart. There were great pain at the seat of injury and profuse hæmaturia which continued in somewhat less degree for four days. On the night of the fourth day the hæmaturia suddenly ceased and a tumour developed in the loin and increased rapidly. An hour later the kidney was exposed in the loin. It was more than twice its normal size, dark purple in colour, and surrounded with blood. The pelvis was enormously distended by clots. The fibrous capsule was not torn. There was a large laceration of the kidney from which protruded beneath the capsule a clot which had dissected the latter from the kidney over nearly the whole of the posterior surface. The capsule was incised and the clot was expressed through the wound by pressure upon the distended pelvis. The kidney at once resumed its normal size and colour. No wound of the pelvis was found. The renal wound was closed with seven catgut sutures and hæmorrhage was completely arrested. A fistula formed after the wound in the loin had been closed for five or six days. Two months later the kidney was exposed through the old incision. Its anterior surface was adherent to the overlying peritoneum. The fistula led to a sac of about the size of a hen's egg on the outer and posterior surface of the kidney. This sac was incised. No communication could be established between its interior and that of the kidney. Part of its walls was excised and drainage was effected through the lumbar incision. The patient rapidly recovered but the fistula had not closed when he was last heard from, two months after the second operation. In six of the seven recorded cases of renal suture the operation was quite successful. In the unsuccessful case the patient made a good recovery from the operation but secondary nephrectomy was performed later with a fatal result. In all the cases suture of the renal wound immediately arrested the hæmorrhage.

BABY SHOWS.

IN THE LANCET of June 20th, 1903, p. 1753, we drew attention to the mischievous effects of baby shows held under the conditions which usually obtain and took exception to the standard of infant excellence thereby encouraged and to the method of awarding prizes to the babies who manifested the greatest degrees of obesity and the heaviest weights in the scales. We pointed out that in the case of infants mere weight was no test of physiological excellence and that high degrees of obesity were of pathological significance and often the results of unsound methods of feeding. We further pointed out that baby shows if properly conducted might be made valuable instruments for educating the public in the best methods of rearing babies and of securing their normal physical development. The necessity for some practical means of educating the public in these respects is abundantly testified by the alarming and progressive fall in the birth-rate and by the huge annual mortality among infants under one year of age. No subsequent measure can compensate for the constitutional disabilities which are engendered by a neglected or mismanaged infancy; no medical or surgical skill can in after years correct the stunted growth and bony deformities which are the direct outcome of injudicious feeding in infancy and of the neglect of ordinary precaution. It is, therefore, with gratification that we notice that at a baby show recently held at the Murphy Memorial Hall, Southwark, most of the prizes were given to breast-fed infants. Another step in the right direction was that evidence of rickets was considered a disqualification. We may, perhaps, take credit to ourselves that our recent remarks in THE LANCET, which were widely reproduced in the lay press, have conduced to this reform and in the hope that it may be fruitful of further reform we would suggest that some of the following points should be taken into consideration in awarding prizes at subsequent baby shows: that as an indication of health the general condition of development and the firmness and elasticity of the tissues should be taken into consideration and not the gross weight of the infant; that the condition of the skin, the muscles, the bones, and the nervous system should be examined and that absence of the stigmata of degeneration, sweating, pot-belly, mouth-breathing, and snuffles, should be considered as points in the competitor's favour. Marks should also be given for evidence of care and attention with regard to clothing and cleanliness. Since perhaps the best test of health in infancy is a regular and steady increase in weight week by week marks might be awarded for the best record in this respect and mothers should be encouraged to take an interest in, and to understand the importance of, a steady normal increment in weight, as opposed to the disadvantages of the abnormal and pathological deposition of fat.

AMBULANCE INSTRUCTION AT MINES.

A MEETING of the North of England Institute of Mining and Mechanical Engineers was held at Keswick on June 10th and in the course of the proceedings a paper on Ambulance Work at Mines was read by Mr. William Leck. This gentleman, who is an inspector of mines, commenced by giving an outline of the work and methods of the St. John Ambulance Association. He said that although there did not appear to be any close connexion between ambulance instruction and the subjects which an institute of mechanical and mining engineers might be expected to take into consideration, yet statistics showed that amongst miners there was a great necessity for ambulance knowledge, as in the year 1901 the inspectors of mines received reports of 1229 deaths at mines and quarries and of 5326 persons injured. The St. John Ambulance Association undertakes the formation of "centres" throughout the country and the Cumberland Mines and Quarries Centre was formed in 1895 by the late Mr. J. L. Hedley, an inspector of mines, as the result of a conference with the mine owners of the county. Mr. Leck then gave some details relative to it. Lord Lonsdale became the president, Mr. Hedley the chairman, and Mr. Leck himself the secretary. The reading of the paper resulted in a discussion which presented some points of interest. Mr. M. H. Habershon of Sheffield suggested that the training of suitable men in the use of apparatus for breathing in noxious atmospheres might be undertaken by such an organisation as the one in Cumberland. He said that with the most recent form of the Giersberg apparatus selected men could breathe for two hours and do light work without discomfort after being properly trained. Dr. Thomas Oliver of Newcastle-upon-Tyne recommended that in the ambulance classes instruction should be given in the treatment of persons overcome by noxious gases or apparently killed by electricity.

LUNACY IN AUSTRALIA.

A BRIEF account of lunacy in Australia, with special reference to New South Wales, was recently published in THE LANCET. The report on lunacy in Queensland, which has just been issued officially, states that on Dec. 31st, 1902, there were 1813 patients under care in the various hospitals and reception houses for the insane in Queensland. During the year the number of patients rose from 1752 to 1813, an increase which is very slightly in excess of the average annual increment. Calculated on the estimated population of Queensland on Dec. 31st, 1902, there were 35 2 persons who were insane for every 10,000 of the general population. The corresponding ratios for the other States were: New South Wales 32·5, Victoria 37·3, South Australia 26·7, and New Zealand 33·4. The number of patients admitted to all institutions in Queensland during the year was 339, comprising 204 males and 135 females. "It is satisfactory to record," says the report, "that the admissions for the last two years have been almost stationary." Hereditary tendency to insanity and alcoholic intemperance were among the chief causes of insanity in the admissions. "The worries and anxieties of the drought did not, as might have been expected, largely increase the admissions." The number of patients discharged as recovered during the year amounted to 131, or 7·3 per cent. of the average number resident. The deaths during the year amounted to 94, or 5·26 per cent. as calculated on the same basis. Of the deaths 21 were due to diseases of the brain and nervous system, 11 to chronic renal disease, 19 to inflammation of the lungs, 21 to pulmonary tuberculosis, and the rest to other causes. Nine of the patients who died from tuberculosis were suffering from the disease on admission to the hospitals. The total cost of the institutions for the year was £50,885 16s., an increase of £4304 over the cost for the previous year. This extra expenditure was entirely due to the drought, with the consequent rise in the price of foodstuffs and the failure of the asylum-grown crops.

THE VENTILATION OF THE HOUSE OF COMMONS.

MUCH time and thought have been devoted to the subject of the ventilation of the House of Commons and it has been generally supposed among sanitary engineers that the method adopted left little to be desired. The "Mother of Parliaments" is, however, as regards her domestic affairs rather a fidgety old lady and in consequence a select committee was last year appointed to investigate the condition of the arrangements for supplying our legislators with the fresh air necessary to sustain them during their arduous exertions. This committee, which consisted of Mr. Akers-Douglas, Mr. Dillon, Dr. R. Farquharson, Sir Michael Foster, Mr. Goddard, Mr. Penn, and Sir John Batty Tuke, met ten times between April and August, 1902, under the presidency of Mr. Akers-Douglas without coming to any definite conclusion. On June 17th, 1903, the committee was re-appointed with Mr. Victor Cavendish and Mr. A. H. Smith in place of Mr. Akers-Douglas and Mr. Penn, and four additional meetings were held with Sir Michael Foster as chairman. The results of these labours are now made public in a couple of reports. Evidence was first heard in regard to the existing mechanism which, as described by Mr. Edward G. Rivers, engineer and surveyor to His Majesty's Office of Works, is as follows. Air taken in on the river front and in certain courtyards is washed by a spray of water and passed through a layer of scrim cloth to remove solid particles. After being heated by steam batteries it enters the chamber through grids under the matting of the gangways and through panels at the ends of the hall. In foggy weather the air is passed through six inches of cotton wool and in summer it can be cooled by blocks of ice placed in the air way. The vitiated air is removed from the upper part of the chamber and passes to an upcast in the Victoria Tower. A thorough examination of the air supplied was made. It was found to contain, with half the seats in the chamber occupied, about 5 parts per 10,000 of carbonic acid and to have a mean temperature of 62° F., with a humidity of from 60 to 72 per cent., while Dr. Graham Smith reported the presence of micro-organisms to the extent of six per litre, no infectious diseases being represented. With the House ordinarily full the amount of fresh air entering was more than 50 cubic feet per minute per head. Altogether, as the committee declares, the air as regards purity "may be said to far exceed that found in many such buildings." Unfortunately, however, "this conclusion, obtained by means of objective tests, is not confirmed by the subjective test of the Members' own feelings." The following recommendations are therefore made: (1) that electrical fans should be substituted for the exhaust furnaces; (2) that the air inlet should be simplified and properly cleaned; (3) that wet screens should replace the water spray; (4) that a more powerful in-take fan should be provided; (5) that the introduction of air under the seats should be tried; (6) that the matting should be removed from the floor of the chamber every day; (7) that there should be frequent general cleaning under the supervision of one person; (8) that a sanitary officer of recognised scientific knowledge and experience should be appointed specially to watch the ventilation; and (9) that inquiries into problems connected with ventilation should be instituted. It will be seen that these recommendations amount to very little in the way of novelty but this is because there is not much room for improvement. The passage of the entering air through matting which is being continually soiled by the boots of Members is certainly objectionable and alteration in this respect was called for. Members will be relieved to learn that they are not being slowly poisoned while assisting in the deliberations of their august House and will be no doubt easily reconciled to the expenditure (over £300 for the fees of witnesses alone) which was incurred in setting their minds at ease.

SOME INTERESTING FACTS IN THE ANNUAL REPORT OF THE COMMISSIONERS OF HIS MAJESTY'S CUSTOMS.

IT is obvious that to a certain extent the annual reports of His Majesty's Customs officers must afford interesting information not only as to the nation's prosperity but as to its moral trend also. For example, the reports show whether an increase or a decrease is taking place as regards the the consumption of alcoholic liquors, of certain taxed foods, and of tobacco. It is thus possible to gather from their pages how far the nation shows in certain directions moral advancement or moral back-sliding. In the report, for instance, recently issued for the year ended March 31st, 1903, there are some interesting fluctuations to be observed in regard to the clearances of alcoholic liquors. The clearance of foreign spirits increased from 8,981,880 gallons in 1901–02 to 9,785,976 gallons in 1902–03, or 9 per cent. It is true that the quantity used for "methylating" has risen enormously on account of the great reduction in the price of foreign spirits, but broadly while a little over 1,000,000 gallons were cleared for "methylating" over 8,000,000 gallons were taken for other purposes. Rum and imitation rum showed an increase of £18,062 this year (0·8 per cent.) and "had it not been for the comparative mildness of the winter the increase," the Commissioners think, "would in all probability have been greater, for prices have been low owing to over-production and to the cheapness of sugar." "Fluctuations in the consumption of rum are difficult to explain," they add; but is it not a fact that rum is used for "blending" purposes? The duty received from brandy showed an increase of one-half per cent. and the Commissioners remark that the consumption of brandy is not so great as it was a few years ago, the decline being mainly attributable to the greater favour extended to whisky. There is a decrease in the amount of brandy cleared in casks and, in spite of an extra duty of 1*s.* per gallon, the increase first alluded to has been due to clearances of brandy in bottle. There has been a great demand for foreign plain spirit and to such an extent as to create considerable competition with British spirits. "Blending" or the pernicious practice of substitutes may possibly account for this increased demand. The consumption of wine has decidedly increased since 1900 and 1901—an "improvement" attributed to the cessation of the war. The stronger wines in cask are chiefly responsible for the increase but lighter wines in cask and sparkling wines in bottles also show an advance. The lighter still wines imported in bottles have diminished, a falling off that has been more marked since the imposition of the extra duty of 1*s.* per gallon on still wine imported in bottles. The greater part of the increase in clearances of heavy wine was in connexion with wines from Portugal. Tobacco shows an increase of 17·8 per cent., which, however, is not wholly due to consumption, for the clearances of the previous year were considerably reduced in anticipation of a rise in duties by forestalments made at the end of the year 1901. It is probable, however, that the normal rate of increase during past years has been maintained in regard to tobacco. Chicory shows practically no change in the quantity cleared; cocoa shows a decrease of 11·5 per cent., chiefly in connexion with raw cocoa and the demands made previously for this article during the war. Coffee shows an increase, while tea remains at much the same figure as last year—that is, the net quantities of duty-paid tea were no less than 254,000,000 pounds. It is to be wished that the Government could exercise as much vigilance over the quality and description of the imported foods and beverages of the nation as it does in collecting every penny that is levied upon them.

PHOTOGRAPHS IN NATURAL COLOURS OF PATHOLOGICAL SUBJECTS.

WE publish this week a coloured supplement in illustration of Dr. W. Hale White's case of diabetic intraocular lipæmia and on the same plate will be seen two photographs in natural colours of a case of purpuric eruption. An account of the case was read before the Dermatological Society of London by Dr. W. Ewart and has been reprinted in the *British Journal of Dermatology.* The patient was a man, aged 30 years, of regular habits and healthy antecedents. He was seized on Dec. 24th, 1902, with sore-throat, trembling, and chilliness though without definite rigor. Two days later he took to his bed and on the 28th the sore-throat disappeared but the left side of his face was swollen. He was admitted to St. George's Hospital on Dec. 30th suffering from typical facial erysipelas. Full doses of perchloride of iron were ordered but as no improvement took place an alkaline mixture was substituted and frequent doses of quinine were given. Under this treatment the patient improved rapidly, the temperature falling to 99° F. on Jan. 3rd and never rising again to any great height. On the evening of the 3rd the first purpuric symptoms were noticed. He had then had 20 grains of quinine and the total amount taken when it was stopped on Jan. 5th was 40 grains. The eruption consisted of small dark purple patches with raised, pink, and intensely tender areolæ. The earliest sites to be attacked were the lower extremities but on the second day the eruption had crept up on to the trunk. Much larger patches were soon formed, partly by coalescence of smaller ones, and the eruption spread on to the back of the thorax and the outer aspects of the upper arms. There was also a patch on the occipital region and there was chemosis of the conjunctiva with subsequent flow of blood-stained tears. The characteristics of the rash were: (1) its occurrence in circular patches; (2) the raised and extremely tender, pink areola; (3) the gradual disappearance of the purple centre which became lighter than the periphery; (4) the occurrence after a few days of considerable œdema of the conjunctivæ, the arms, the legs, the back, and the thighs; (5) the obvious localisation at the points of pressure; and (6) the formation of bullæ which necrosed and left superficial ulcers. As regards the causation of the rash considerable interest was attached to it owing to the fact that the patient had been taking large doses of quinine. It was at first impossible to determine whether the purpura was the result of quinine intoxication or was connected with the erysipelas but later the patient, who had nearly recovered, took more large doses of quinine with no recurrence of the eruption. The photographs in colours, which we reproduce, were taken by Messrs. Sanger, Shepherd, and Co., by certain improved appliances recently introduced by them, and we are informed by Dr. Ewart that they are excellent; we are also informed that several members of the medical profession have now applied the process successfully to their work and that the appliances for colour photography have been added to the laboratory of one of the metropolitan hospitals. A year ago the process employed by Messrs. Sanger, Shepherd, and Co. was successfully applied to the photo-micrography of stained bacteria. A considerable advantage is gained in lantern slides (three and a quarter inches in diameter) made by this method directly through the microscope, the colours of the stained bacteria being rendered correctly. The brilliancy and sharpness of the image are even greater than when actually viewed through the eyepiece of the microscope and when the eyepiece is inserted in the lantern and focussed upon the screen the enlargement of detail possible is, of course, very great.

SOUTH AFRICAN SANATORIUMS FOR THE TREATMENT OF CONSUMPTIVES.

WE have received the particulars of a scheme initiated by the directors of a company bearing the name "Cradock Sanatorium and Thermal Baths" with the object of establishing sanatoriums for consumptives in South Africa. There is no need for us to comment on the advantages which the climate of South Africa offers for the treatment of tuberculosis; they are too well known. Owing to several circumstances it has been found extremely difficult, if not impossible, to form charitable institutions for the relief of necessitous patients in suitable districts in South Africa. A company, however, has been floated to form a hydropathic establishment and sanatorium at Cradock, where there exist a number of mineral and warm sulphur springs. The directors also propose to form a separate section of the company for the purpose of building and equipping a sanatorium solely for the employment of the "open-air" method of treatment. It is proposed to solicit the required capital from the public and to guarantee interest at the rate of 3 per cent. per annum. Up to this point it might well be considered that the proposal is purely a financial one. It has, however (and this is the reason that we wish to draw attention to the scheme), a philanthropic side. A careful estimate has been made of the probable revenue and expenditure and it is estimated that out of the income received from paying patients it will be possible to receive, and to give all the benefits of the sanatorium to, a certain number of cases gratuitously. Thus the institution will not only be self-supporting but will also be doing a charitable work in the care and treatment of poor patients. The whole scheme is a very ambitious one. Whilst proposing to start with buildings capable of accommodating 40 patients, it is intended that similar sanatoriums may be erected in various districts of South Africa especially adapted by climatic and other conditions to the treatment of tuberculosis. It is hoped that patients will thus reap the benefit of constant change of air and scenery, since a series of sanatoriums will enable them to be transferred from one place to another should indications point to the desirability of a move. We feel confident that such a scheme as we have just outlined is well worthy of support. The position of many patients who proceed to South Africa on account of being victims to tuberculosis is a deplorable one and a sanatorium for necessitous individuals is much to be desired. We sincerely trust that the necessary funds will be forthcoming. We may add that it is proposed to form a medical advisory board in London, to which applications for admission would have to be made. Mr. D. C. Lauer, one of the directors, is now in England in order to make the necessary preliminary arrangements.

THE CHAIR OF PHYSIOLOGY IN THE UNIVERSITY OF MELBOURNE.

OWING to the appointment of Dr. C. J. Martin as director of the Lister Institute of Preventive Medicine the chair of physiology is vacant at the University of Melbourne. Particulars as to duties and emoluments can be obtained from the Agent-General for Victoria. The new professor will be required to commence work on March 1st, 1904.

KING'S COLLEGE HOSPITAL.

A SPECIAL court of the corporation of the president, vice-presidents, and governors of King's College Hospital will be held in the large theatre of King's College, Strand, on Monday, Oct. 12th, at 4 o'clock in the afternoon, for the purpose of obtaining the sanction of the members of the said corporation to the removal of the hospital from its present site to a site in South London, which proposed removal is put forward at the initiation of both the council and the committee of management.

HÆMOPHILIA.

IN THE LANCET of Oct. 3rd, p. 958, we published a case of persistent secondary hæmorrhage after enucleation of the eyeball for sarcoma which was under the care of Sir William J. Collins. The history of troublesome hæmorrhage on several previous occasions clearly showed it to be a case of hæmophilia. Very many cases of hæmophilia have been observed and yet it cannot be said that we are materially nearer a knowledge of its true pathology. It is generally accepted that there is no demonstrable alteration in the walls of the bloodvessels. The chemical composition of the blood in hæmophiliacs does not manifest any abnormality and the time required for coagulation is not greater than is needed by the blood of those in health. There is, however, one important difference. When profuse hæmorrhage occurs in a healthy person the coagulability of the blood steadily rises, for a time at least, so that the arrest of the hæmorrhage is assisted; but in those who suffer from hæmophilia the coagulability of the blood diminishes as the amount lost increases. The only point about the etiology of the disease which is indubitable is its transmissibility through the female line, the members of which are themselves unaffected, but in this hæmophilia is not peculiar, for a similar mode of transmission appears to obtain in pseudo-hypertrophic palsy and other conditions. The first clear description of hæmophilia was given by Sir William Fordyce in 1784 and Dr. J. C. Otto in 1803 described the disease in a family where it had occurred for nearly 80 years. Our knowledge of the etiology and pathology of hæmophilia is unsatisfactory but still more unsatisfactory is the treatment. Several drugs, such as chloride of calcium and ergot, have been credited with some power in stopping the hæmorrhage and probably in some cases they do good but certainly in other cases they do not prove of the slightest avail. It is to be hoped that preparations of the suprarenal gland will be of use and they deserve an extended trial though, in Sir William Collins's case already referred to, adrenalin solution did not arrest the hæmorrhage. The most important part of the treatment is prophylaxis. As far as possible all wounds should be avoided and only absolutely compulsory operations should be performed.

"DECAPODS" AND THEIR DANGERS.

THERE seems to be a general movement amongst the managers of our suburban railways to introduce rapidly starting trains and already on two lines engines for that purpose have been designed which are known as "decapods." It may be assumed that this name has its origin in the number of wheels on the engines which, we believe, are "braced." It is stated that these engines are capable of getting up a speed of 30 miles an hour within 30 seconds of making a start and that in consequence much time is saved at the end of the journey. We have no desire to discourage the attempts that are being made to secure punctuality and despatch with regard to our suburban railway service—there is room for improvement; but, above all, we should prefer to see more attention given to increased accommodation rather than to the sudden getting up of speed. It seems to us that if the system of "decapods" or rapidly starting engines is universally adopted some alteration in the method of admitting passengers to the platform must be made. The system of shutting all entrances to the platform 50 seconds before the train is timed to start, as is the rule in the United States, would become imperative. It is stated that the guards of the "decapod" train are compelled to be well inside their compartments if they wish to run no risks before giving the signal by whistle to start. If that be so, what is likely to happen to the passenger who attempts to enter the train whilst it is in motion? Apart from this aspect of the proposed innovation the question of the effect on passengers of suddenly attaining a speed of 30 miles an hour has to be considered. The policy of the "decapod" is, we think, a mistake and it seems to us that a more rational means of dealing with the congestion and expedition of railway traffic could be devised. The career of the "decapod" from start to finish would seem to be necessarily hazardous. A rapid start, for instance, made in foggy weather when there proved to be a train at a standstill not far ahead might be the preface to very serious consequences.

NORMALLY UNEQUAL GROWTH AS A POSSIBLE CAUSE OF DEATH.

THE subject of comparative pathology is an important branch of biological science of which as yet the merest fringe has been studied and it thus offers splendid opportunities for research, the results of which may probably be of very great value in human pathology and in elucidating the causes of variation in type of diseases affecting man and the lower animals. Mr. Frank E. Beddard, F.R.S., whose great experience as prosector at the gardens of the Zoological Society invests his observations with great weight in these matters, records in an interesting letter to *Nature* of Sept 24th, p. 497, a condition of the circulatory system of the Japanese salamander (*Megalobatrachus japonicus*) which he regards as a result of a normally unequal process of growth and which he suggests as a cause of death—"a truly 'natural' cause of death," as he expresses it. He states that as a result of a good many years' experience he has frequently found it difficult to assign any definite cause of death to the lower vertebrata which die in the gardens of the Zoological Society. In the animal under consideration, which had lived 19 years in the gardens and was some three feet in length, no obvious signs of disease were found in any organ. Judged by its length it must have been old, for a specimen three feet long is stated to have been at least 52 years old.[1] On comparing the heart of this animal with that of another specimen some 20 inches in length, Mr. Beddard found, as he expected, that it was larger and that its subdivisions maintained their relative proportions, but in the larger animal the two sets of valves at the anterior and posterior ends of the pylangium were so small in relation to the lumen of the tube that they would not meet in the middle line and were thus incompetent, while in the smaller salamander they were large enough in relation to the size of the tube to close it completely. Mr. Beddard therefore suggests that these valves in the process of growth do not increase *pari passu* with the general increase in size of the heart and the conus arteriosus. Admitting the accuracy of the observation there are, however, some difficulties in accepting Mr. Beddard's view that this condition should be regarded as the result of a normal process of growth or even as a probable cause of death. In the first place it is difficult to see any *a priori* reason why the valve curtains should not share the general tendency to progressive growth; their failure to do so rather points to a defect of growth and it would be of interest to know the microscopical condition of the cusps and of the wall of the pylangium. It certainly comes as somewhat of a shock to regard a normal process of growth as tending towards death. Again, while it is certain that the condition described would interfere with the circulation, it is obvious that it must be of very gradual development and it might be expected that a defect of this kind would be compensated more or less completely by an increased growth of heart muscle, which apparently did not occur in this case, and that if not so compensated some pathological effects would be discoverable in other organs. On the other hand, that regurgitation can be produced by defective coaptation of healthy valve curtains in the case of both the mitral and the tricuspid valves in man owing to dilatation of these orifices is a fact in human cardiac physics now almost universally admitted, and by some observers a similar condition at the pulmonary or even aortic orifice is believed to occur. Moreover, Mr. Beddard quotes a record of a dissection by Hyrtl of an animal two and a half feet in length in which the valves were figured of small size relatively to the lumen of the vessel, though according to Mr. Beddard incorrectly in some particulars of structure. In any case the observation is of great interest and should direct the attention of those with opportunities for dissection of lower vertebrata to this question, more especially to determine if the condition is frequent and whether it is of normal or pathological origin.

DENTAL OPERATIONS UNDER CHLOROFORM.

A RECENT death under chloroform which occurred at Manchester draws attention once more to the danger of using chloroform as an anæsthetic for dental operations unless there is exceptional and convincing reason for its selection. We are not at the moment, however, specially concerned with this aspect of the case but rather with the remarks made upon it by the coroner if the general press, our only present source of knowledge in the case, may be taken as giving a correct account. According to one version we have read the coroner in his remarks to the jury stated that he had a great objection to the administration of chloroform for the extraction of teeth. So far we are, generally speaking, entirely in accord with him. The coroner, however, is reported to have continued by saying that the extraction of teeth should be accomplished without any anæsthetic drug whatever. We cannot believe that the coroner made such a perfectly unjustifiable generalisation. Not only would a needless amount of pain be inflicted upon the public were anæsthetics not employed for dental operations but these operations would also be increased in number. A number of extractions that can be safely performed at one sitting upon an individual when anæsthetised could not be borne by a conscious individual, and, moreover, there are plenty of cases in which the operation would actually be dangerous by the pain and shock to a conscious person when it is free from danger to the individual skilfully anæsthetised with nitrous oxide or ether The coroner s remarks in this case, as well as the case itself, should help to enforce a principle that we have insisted upon before now—viz that if there is any question of the necessity for chloroform in a dental operation the drug should not be administered without the presence of someone experienced in the use of anæsthetics There is no question that a considerable number of fatalities would be avoided every year if such a principle were everywhere acted upon

THE OUTBREAK OF CHOLERA IN SYRIA

THE details given in our present issue of the epidemic of cholera in Syria by the British delegate to the Ottoman Board of Health are deserving of serious attention, for it is evident that although the Egyptian Government was successful in combating cholera when it appeared in Egypt in 1902 yet the progress of the disease was not checked, for notwithstanding every effort to limit its extension the infection was carried into Syria and is there spreading over the greater part of that country Cholera, as is shown, was not long in reaching Damascus and by August of this year some 223 deaths were reported The villages around Damascus soon became infected and from there the disease seems to have advanced steadily northwards It has been epidemic at Hama, a town about half way between Damascus and Aleppo, and as in the vicinity of Damascus so in the neighbourhood of Hama a large number of villages are suffering from the disease The news received from these villages is scanty and intermittent and there is reason to believe that the extension of the disease is greater than is likely to be gathered from occasional telegrams In many instances, it is stated, the name of a village has only been notified after the disease has been present for weeks and has already caused a high mortality From Telhab the earliest announcement was that the mortality from cholera was ten per day, while almost the first notice of cholera in the village of Rebebó was the announcement of 350 cases with 310 deaths Cholera has not yet reached the town of Aleppo but it is in the vilayet of that name and has advanced well on its way to Antioch Tripoli is the only seaport town reported in which the disease has become epidemic In August the inhabitants were in a state of panic and were leaving the city by land and by sea, so that there is every probability of the infection being distributed in many directions Beirut is mentioned as one of the places to which the disease has been carried by refugees Besides spreading to the coast the cholera has also travelled as far as Biredjik, an important town on the Euphrates, where it is feared it will have opportunities of extending to Armenia on the one side and to Mesopotamia on the other

THE International Sanitary Convention is about to hold a meeting in Paris, the delegates not having met since the convention at Paris in 1897 The British delegates are Mr Maurice de Bunsen, Secretary of Embassy in Paris, Dr F G Clemow, representative of the International Sanitary Board at Constantinople, Dr Theodore Thomson of the Local Government Board, Colonel Richardson of the India Office, and Dr M Armand Ruffer, President of the Sanitary and Maritime Quarantine Council of Egypt

THE new east block of the Mount Vernon Hospital for Consumption and Diseases of the Chest at Hampstead will be opened by the Marquis of Zetland, K T, the President of the hospital, on Tuesday, Oct 27th, at 3 o clock Communications on the subject should be addressed to Mr J Morton, the secretary of the hospital, at his office, 7, Fitzroy square, W Last year this hospital received a handsome donation of £121 000

As regards plague in the Mauritius a telegram from the Governor received at the Colonial Office on Oct 2nd states that for the week ending Oct 1st there were 57 cases of bubonic plague and 37 deaths As regards the Cape Colony the medical officer of health of the colony states that for the week *ending Sept. 12th the only cases of plague notified* were 1 at Port Elizabeth and 1 at East London

THE annual dinner of the Association of Public Vaccinators of England and Wales will take place at the Hotel Cecil, Strand, W C, on Friday, Oct 23rd, at 7 P M Communications on the subject should be addressed to Mr Charles Greenwood, the organising secretary, at the offices of the association 1, Mitre Court buildings, Temple, E C The association has now been established for five years

THE King has granted to Dr F M Sandwith His Majesty's Royal licence and authority that he may accept and wear the Insignia of the Third Class of the Order of the Osmanieh, conferred upon him by His Highness the Khedive of Egypt, authorised by His Imperial Majesty the Sultan of Turkey, in recognition of valuable services rendered by him

THE death of Mr W J Walsham F R C S Eng, surgeon to St. Bartholomew s Hospital, is announced as taking place on Oct 5th Mr Walsham had been ill for some weeks and had only just returned from Wiesbaden, whither he had gone for the benefit of his health We shall publish an extended notice of his career in a future issue

Dr B A Whitelegge, C B, His Majesty's Chief Inspector of Factories, has been appointed President of the Epidemiological Society in the place of the late Dr W H Corfield

THE M D DEGREE OF BRUSSELS.

BY N LEONARD, M D BRUX., M R C S ENG,
L R C P LOND

I HAVE had several letters from members of the profession who are strangers to me asking for particulars as to the general requirements of the M D Brux examination This induces me to think that a large number of medical men in England are interested in the examination and would be glad to know something of it from one who has been ' through the mill And, again the fact that one reads in almost every issue of the medical press complaints against the English Royal Colleges and other licensing bodies that their Members and Licentiates are prevented from obtaining the much coveted title of M D influences me to give a *résume* of the examination which may possibly induce others to enter for the Brussels degree and so find a satisfactory solution to the difficulty

In an endeavour to give a lucid description of the examination my remarks naturally fall into the following sections a recapitulation of the regulations of the examination as set forth in the printed syllabus of the University, and a detailed account of the method of examination, including specimen questions in the several parts While giving, also, some idea of the general standard required and the relative difficulty of the different subjects, I shall also mention the books usually read

The regulations as set forth by the University are briefly as follows The examination, which is conducted *viva voce* in English, consists of three parts, viz —First Part (1) General medicine, (2) general therapeutics, materia medica, and pharmacology, (3) pathology and morbid anatomy, and (4) special therapeutics and medicine of internal diseases, including mental diseases

Second Part: (1) Surgery (theoretical); (2) theory of midwifery; (3) public and private hygiene; and (4) medical jurisprudence. Third Part: Clinical examinations on patients in (1) medicine, (2) surgery, and (3) ophthalmology; (4) practical midwifery examination; (5) operative surgery examination; and (6) regional anatomy, with dissections. Fees and charges: Matriculation fee, £8 12*s.*; for the three examinations—First Part £4 8*s.*, Second Part £4 4*s.*, Third Part £4 8*s.*; legalisation of the diploma 8*s.*, making a total of £22. Examinations take place on the first Tuesday in November, December, February, May, and June, and usually last from seven to nine days, so that candidates need not be absent from their professional duties longer than 11 days at the outside. Or the three examinations may be taken separately by those who are unable to be absent from home so long, but in such a case the matriculation fee of £8 12*s.* must be renewed. According to the printed syllabus the examination is conducted in English through the medium of an interpreter, but it will be found that the majority of the examiners speak excellent English, as do most people in Brussels, so that the services of the interpreter are dispensed with through the major portion of the examination. Copies of the printed regulations may be obtained by writing to the University or to Dr. Reeve, 2, Harewood-place, Hanover-square, London, W.

The whole of the theoretical part of the examination is *vivâ voce*, each of the *vivâs* in the general subjects lasting from 15 to 20 minutes. In most of them only *one* question is asked and the candidate is then expected to "talk" on that subject for the required time. For example, he may be asked to describe a typical case of typhoid fever. The examiner settles down to listen, making no remarks during the course of the candidate's answer, but merely notifying him at the expiration of his stipulated time that the *vivâ* is ended. It is in this main point that the *vivâ* at Brussels differs from that in England, for here the examiner showers questions on the candidate which require but short answers, often merely "Yes" or "No," whereas in Brussels one must be prepared to give a kind of lecture by way of reply. As a rule, only general questions are asked, and on topics that the average man in general practice should have a good knowledge of. But some of the *vivâs*—and important ones from the Belgian standpoint—may require considerable reading to prepare for, notably those in pathology and pharmacology, the standard of which at Brussels considerably exceeds that required by the Conjoint Board in London. The *vivâ* in theoretical midwifery is rather different, inasmuch as the examiner does not confine himself to one question but divides his time between embryology and midwifery proper. Considerable stress is laid on the subject of embryology, but one can get up all that is required from the first 90 pages of Galabin's "Manual of Midwifery." The Third Part of the examination presents some difficulties, particularly to the man who has left his hospital days long behind him, as the regulations require him to be familiar with anatomy and, in addition, to dissect some part. Ophthalmology, although little stress is laid on it, may also cause some trouble to one who has had little experience in that branch. Still, the cases are generally simple and straightforward and will be easily overcome by a little reading up of the subject.

I propose now to give a specimen question or two in each subject of the examination in order that the prospective candidate may thoroughly understand what is expected of him.

FIRST PART.

1. *General Medicine.*—Describe a case of cirrhosis of the liver. Describe a case of cholera.

2. *Materia Medica and Therapeutics.*—What do you know of belladonna? (You are expected to give its source, dose, preparations, actions, and therapeutical uses.)

3. *Pathology.*—What do you know of cancer? (The examiner requires a brief description of the various kinds, their usual situations at onset, their mode of spreading, their microscopical appearances, and, possibly, your theories as to its cause.) What is the pathology of tuberculosis of the bones of the spinal column?

(No microscopical specimens are given.)

4. A fourth *vivâ* of ten minutes' duration is given on methods of staining microscopic sections and the elements of bacteriology.

SECOND PART.

[illegible] at 8 A.M.).—General questions on frac- [illegible] diseases, with treatment and prognosis. [illegible] detail the macroscopical and microscopical [illegible] and explain its formation. Describe the [illegible] changes which take place in it at birth. [illegible] and give your treatment. Describe the methods of producing premature labour.

3. *Hygiene.*—Methods of ventilation in a private house, water and its impurities, &c.

4. *Medical Jurisprudence.*—Drowning and its diagnosis. Hysteria and its relation to kleptomania, &c.

THIRD PART.

1. *Clinical Medicine* (held at 8.30 A.M. on Sunday).—Clinical cases in the wards, one case being given to each candidate and questions being asked of the patient through the medium of the interpreter. Plenty of time is given, the candidate not being limited to ten minutes as at the English Conjoint Board examinations, but a full examination of the patient must be made and candidates must be prepared to discuss the case with the examiner like the commentaries required in the higher examinations of the English universities.

2. *Clinical Surgery* (at 8 A.M.).—Cases are selected at random from those waiting to be seen in the surgery. One case is allotted to each candidate. The same remarks as applied to the clinical medicine hold good for the surgery.

3. *Ophthalmology.*—Simple clinical cases as mentioned above—e.g., granular conjunctivitis, corneal ulcer, &c.

4. *Practical Midwifery.*—Use of the forceps, demonstration of "mechanisms" of labour, and the usual operations on the mannikin (model of pelvis).

5.. *Operative Surgery.*—One or more actual operations are required to be performed on the cadaver, usually simple ones, such as the amputation of a toe, the ligature of an artery, or one of the commoner amputations on a limb. The candidate will also be asked to mark out with coloured chalk the line of incision and to describe verbally the more difficult operations. He must also be familiar with surface marking, particularly for trephining.

6. *Dissections.*—The most commonly required are the palm of the hand, the dorsum of the foot, Scarpa's triangle, and anticubital fossa. One is not expected to make a particularly neat dissection, as the time is limited to two hours, but anatomical questions will be asked afterwards on the particular part dissected.

The general standard of the examination is, on the whole, rather lower than that of the English Royal Colleges; in some subjects the examination is more difficult and in others it is considerably easier. The relative difficulty of the subjects is approximately as follows: materia medica, therapeutics, pathology, and operative surgery, above Conjoint Board standard; medicine (theoretical and clinical), midwifery (theoretical and practical), and ophthalmology, similar to Conjoint Board standard; surgery (theoretical and clinical), dissections (with anatomical *vivâ*), public health, and medical jurisprudence, below Conjoint Board standard. Honours are granted in each part on the same lines as at the English universities to candidates who obtain a certain percentage of marks.

The books generally read, and which I should recommend, are as follows. Medicine: Taylor's "Practice of Medicine." Materia Medica and Therapeutics: Hale White's "Materia Medica" and Lauder Brunton's "Action of Medicines." Pathology: Bowlby's "Surgical Pathology," and Green for reference purposes. Surgery: Rose and Carless or Walsham. Midwifery: Galabin's "Manual of Midwifery" and Herman's "Difficult Labour." Ophthalmology: Jessop's "Ophthalmic Medicine and Surgery." Operative Surgery: Waring's "Manual of Operative Surgery." Anatomy: Gray.

The total cost to the average candidate, including examination fees, residence in Brussels, return passage, and coaching fees (and I would strongly advise coaching by correspondence), would be about £40, as residence in the Belgian capital is remarkably cheap, especially at the English "pensions" on the Boulevard de Waterloo.

The average percentage of failures recently is 50 to 60, which is rather disheartening, but is easily accounted for by the fact that the foreign candidate under-estimates the standard of the examination, particularly in the stiffest subjects—namely, therapeutics and pathology.

Fuller particulars than one can give in the limited space of a short paper will be found in Dr. Henchley's little book, recently published ("The M.D. Examination of Brussels University," by A. R. Henchley, M.D. London: Mitchell, Hughes, and Clarke. 2*s.* 6*d.*).

I trust that these remarks may be helpful to those of my profession who are considering the advisability of entering for the Brussels degree, which I honestly believe to be well worth the time, trouble, and expense spent upon it. I feel confident that the possession of the degree will amply repay them in social status for the worry and anxiety always associated with an examination.

VACCINATION GRANT.—Mr. Legh Richmond Marshall has received the Government grant for efficiency in vaccination as public vaccinator in the Mary Tavy district of the Tavistock union.

BORIC ACID IN MILK.—The Exeter city council has issued a circular to the vendors of milk in that city drawing their attention to the fact that the addition of boric acid to milk is an offence under the Sale of Food and Drugs Act.

ANNUAL REPORT (FOR 1901) OF THE REGISTRAR-GENERAL OF ENGLAND AND WALES.

II.[1]

AMONG the many purposes served by the national records of English mortality from specified causes is this—that they constitute a standard by which may be measured the mortality from corresponding causes in particular administrative counties, urban and rural sanitary districts, the sanitary circumstances of which are, or ought to be, under constant medical supervision. In our editorial capacity we are frequently applied to by medical officers of health for standard data of this nature needed by them for the compilation of their local reports; and here we pause to remind our official correspondents that within six weeks of the close of each year the Registrar-General publishes in his return for the fourth quarter the vital statistics concerning the country generally, the inclusion of which in the annual reports of medical officers of health is required by the Local Government Board.

To return to the volume before us, we notice that in the report for 1901 an attempt has for the first time been made to establish a *norma* with which the several death-rates, not for urban districts alone but for rural districts also, may properly be compared.

In consequence of the changes in the character of rural communities that are constantly being effected by the "urbanising process" everywhere going on accurate discrimination between urban and rural aggregates of administrative areas is found to be impracticable. The following expedient, however, has been adopted as the best attainable in present circumstances. A selection from among the English counties has been made so as to show in one list certain counties that are chiefly urban in character and contain most of the industrial centres, and in another list certain counties that are exclusively rural or that contain only a few small towns which, although technically styled urban, nevertheless partake of that character to a slight degree only. In this way a rough sorting of counties into urban and rural has been established which, although not ideally perfect, will nevertheless usefully serve the object in view—namely, that of furnishing criteria by which the health conditions of individual urban and rural areas respectively may be tested.

In the case of such diseases as pulmonary phthisis, enteric fever, diarrhœa, or pneumonia it would be futile to compare the mortality in a distinctively rural area such as that of Shropshire or of Somersetshire with the corresponding mortality in England and Wales, more than half of the population of which is essentially urban in character. Equally futile would it be to compare with the same standard the mortality from any of these diseases in a vast urban community like that of Manchester or Birmingham, for it will readily appear on reference to the tables that the mortality from every one of the diseases mentioned is enormously greater amid the unhealthy conditions of our crowded towns than in the sparsely populated areas of our country districts. Therefore, in order that the mortality from a given cause in a rural area may be rendered fairly comparable with that in an urban area allowance must be made for differences of age constitution of the population.

In the earlier portion of this report a table is given which shows that almost without exception the mortality in the several counties that are mainly urban has been increased, whilst that in the mainly rural counties has been reduced, by correction for the differences referred to. That this is the case will clearly appear if the mortality of Lancashire, an essentially urban county, be contrasted with that of Norfolk, which is mainly rural; for whilst the rates of mortality uncorrected for age differences of population show an excess in the case of Lancashire amounting to only 20 per cent., the corrected rates show an excess of 53 per cent. The explanation is obvious, for whereas in the increasing population of Lancashire 85 per cent. of the people are found living at ages from five to 65 years, and only 15 per cent. at ages outside these limits, in the relatively stationary population of Norfolk the proportions are 81 and 19 per cent. respectively. Thus, of the population exposed to the high risk of mortality attaching to the beginning and the end of life there is a much larger proportion living in Norfolk than in Lancashire. It is, therefore, apparent that wherever great differences exist in the age constitution of communities their several death-rates must be modified in order to allow of valid comparison.

Tuberculosis and cancer, two diseases the prevalence of which has recently engrossed a large share of public attention, are treated of in considerable detail in the present report. From an interesting table which compares the mortality from pulmonary phthisis at several age groups in quinquennial periods at the beginning and the end of the last quarter of a century we learn that in 1901 this disease was fatal to 1487 per 1,000,000 of the male population of England and to 1055 of the female, the male rate having decreased since 1876-80 by 28 per cent. and the female rate by not less than 42 per cent. Among both males and females the reduction in the death-rate has been greatest at ages below 35 years. Males suffered more severely than females in London and in most of the other English counties, the male rate of mortality from this disease in the county of Warwick being nearly double the female rate. After correction for age differences in the several populations the death-rate from pulmonary phthisis among males at all ages is higher in the urban than in the rural counties by 29 per cent., whilst among females the urban and rural rates are practically identical. When, however, separate account is taken of the mortality at particular ages it is found that among persons of both sexes at ages from 15 to 35 years the disease is more fatal in the rural districts than in the urban, whilst at all other ages the reverse is the case. This apparent exception in favour of the towns suggests comparison with the case of pneumonia, the mortality from which disease is greater at all ages in the town than in the country. The explanation probably lies either in the circumstance that migration frequently takes place of young country-bred adults to the towns or in the nature of the diseases themselves. It may reasonably be supposed that as a rule the more vigorous of the young people are attracted to the towns in expectation of lucrative employment and we know that a portion of these eventually fall victims either to pulmonary phthisis or to pneumonia. The course of the former disease is generally chronic, its victims tending to become incapable of sustained exertion for a considerable period before death. The course of pneumonia, on the other hand, is generally so rapid as to prevent the patient's removal to long distances from the place of attack. Consequently, in the former case many of the patients return to their native places and their deaths are there recorded; in the latter case such return will almost certainly be the exception. Moreover, the longer the period of residence in a town the less is the probability of return to the country in case of disablement; in the first place, the previous home is less likely to be available, and in the second place the patient is more likely to be tied to the town by the responsibilities of a family.

From these considerations it might almost have been foreseen that the increase of mortality from pulmonary phthisis in rural districts caused by the return of natives from the towns would be limited to a small group of ages. The table shows that this has actually been the case, for in both sexes after the thirty-fifth year this mortality in the rural counties is seen to be much lower than in the urban.

From cancer the mortality in England and Wales during 1901 was the highest on record. Among males it was fatal at the rate of 691 per 1,000,000 living, which exceeded the decennial average rate by 16 per cent. Among females the rate was 985 per 1,000,000, or 9 per cent. in excess of the average. The present report contains two new tables which show for males and for females separately the relative frequency with which cancer affects the different parts of the body. The ages at death of the victims to cancer are also stated. The statistics of 1901 confirm those of previous years in showing that malignant disease is much more fatal among women than among men, but it still remains true that this is because of the tendency of cancer to affect the generative and mammary organs of the female rather than those of the male. In the year 1901 the male deaths from malignant disease less those from affections of the organs referred to were equal to a rate of 673 per 1,000,000 living, whilst the female rate with the same limitation did not exceed 575 per 1,000,000. It is in the case of diseases like cancer, which are fatal chiefly at particular ages, that the necessity of correction of the death-rates after the method already referred to is especially apparent. The mortality from malignant disease at ages below 35 years is small and is generally disregarded, but if the cancer mortality in 1901 at all ages over 35 years be judged of by the uncorrected rates it will appear to be higher in the rural counties than in the urban, whereas if the corrected rates be examined the opposite conclusion follows, for the rural mortality is in that case shown to be the lower. In the calculation of local cancer rates of mortality a serious complication arises from the occurrence of the deaths of many country patients in the hospitals of our great towns and their registration there. In addition to this it would be absurd to assume that the place of every patient's last residence before death had been also the place of origin of his disease.

---

[1] The first notice was published in THE LANCET of Sept. 26th, p. 900.

Among the other interesting matters dealt with in the present volume we have only space left to notice one more section which now appears for the first time—namely, that relating to infantile mortality. The mortality among infants and very young children has always been regarded as a valuable test of salubrity and for this reason Dr. Tatham has thought well to devote to it special attention in the present report. Two important new tables have now been inserted. In one of them the mortality of infants under one year of age is calculated in terms of registered births in 1901, and in the other the mortality of children under five years old is shown as a proportion of the population estimated to be living at that age in the middle of the year. These tables have been prepared to show the death-rates from several causes in each of the English counties but on examining critically the local mortality very great differences became manifest according as the areas selected are urban or rural in character. In another pair of tables the mortality in the urban and rural list of counties before referred to is shown, from which it appears that both among infants in their first year and among children of less than five years the mortality is considerably greater in the urban group of counties than in the rural, and this is true whether the total mortality or the mortality from all the specified causes (with one exception) is put in comparison. It is noteworthy that at ages under one year as well as at ages under five years, boys die more rapidly than do girls and this is the case with respect to the rural quite as markedly as to the urban districts.

In concluding our notice of this report we need only say that in its present greatly improved form it will be found a serviceable and almost indispensable addition to the library of the medical officer of health.

THE CHOLERA EPIDEMIC IN SYRIA.

(From the British Delegate to the Ottoman Board of Health.)

That a great part of the Syrian interior, and to a less extent the coast, has been and is still being seriously ravaged by cholera there is unfortunately no room to doubt. The probability of a still more extensive spread of the disease in the near East and of its ultimate appearance in Europe itself is so great that serious attention may be usefully directed to the course the disease has followed hitherto, and no apology is needed for giving in some detail what is known of its behaviour in Syria during the past few months. Before doing so it will be convenient to recall the history of the epidemic in the Turkish empire since it first appeared there some year and a half ago. This has been already given in detail in successive letters to The Lancet[1] and may be briefly summarised here.

Cholera broke out among the pilgrims to Mecca and Medina early in March, 1902. It caused a considerable but not excessive mortality among them, and at the end of the pilgrimage almost disappeared from the Hedjaz. At the end of May it appeared in the Yemen and through the summer and autumn was seriously prevalent in several places along this portion of the Arabian coast, as also at Yambo and elsewhere. It reappeared in Medina in September. The Assyr province has also been the scene of a rather serious outbreak. Cholera was first recognised in Egypt in July and caused a widespread, though not a remarkably intense, epidemic, which lasted through the autumn and the early part of the winter. From Egypt cholera was carried to Syria at the end of September. It was the cause of a considerable mortality on the coast and in the interior of Palestine; it appeared in the Hauran, and at the end of November it was reported from Damascus. It was epidemic here until the middle of February, when it disappeared only to break out again a month later. Through the later months of the winter and early spring the disease was confined to Damascus. Its subsequent course here has been as follows.

Throughout the month of April the number of cases of, and deaths from, cholera in Damascus varied from between *nil* and three each day. Towards the end of the month there were several days together during which no fresh case was reported. But occasional cases continued to occur through April and May, and towards the end of May it was officially admitted that the disease had appeared in several villages outside the town of Damascus itself. In the town the official figures would indicate that the cholera remained comparatively quiescent, causing only sporadic cases, until the second week in July, when it became more active, and that since that date it has been truly epidemic. The following are the figures published in the official bulletins since the beginning of the recrudescence of cholera on March 18th last:—

Cholera in Damascus.

Date.	Cases.	Deaths.
From March 18th to May 3rd	77	87
,, May 4th ,, ,, 11th	4	5
,, ,, 12th ,, ,, 17th	3	2
,, ,, 18th ,, ,, 24th	9	7
,, ,, 25th ,, ,, 30th	4	4
,, ,, 31st ,, June 7th	1	1
,, June 8th ,, ,, 11th	2	2
,, ,, 12th ,, ,, 20th	5	4
,, ,, 21st ,, ,, 28th	6	7
,, ,, 29th ,, July 4th	10	13
,, July 5th ,, ,, 12th	8	7
,, ,, 13th ,, ,, 18th	48	23
,, ,, 19th ,, ,, 26th	31	31
,, ,, 27th ,, August 1st...	29	19
,, August 2nd ,, ,, 8th	20	11
Totals	257	223

The totals are believed to be very considerably below the truth.

The first known cases of cholera outside Damascus during the present summer occurred at Katana, the centre of a district of the same name, situated some "three hours" (say, 15 miles) to the south-west of Damascus. On inquiry, it was ascertained that on May 24th a woman inhabiting Katana was attacked with symptoms of cholera but recovered Her father fell ill on the morning of the 25th and died at 11 o'clock the same night. Three other persons were attacked on the same day and died after illnesses varying from five and a half to 20 hours. Another death occurred on the 26th; the patient, a woman, had suffered from diarrhœa for several days previously. On the 27th a seventh person, a man, was taken ill at 6 o'clock in the evening and died seven hours later. Cases continued to occur here until June 26th, since which date Katana has disappeared from the bulletins. It is not, however, quite clear whether this indicates a complete cessation of the epidemic there.

On June 1st news was received of the appearance of cholera at Zebdani, some 20 miles to the north west of Damascus, and having a station on the line of railway from Beirût. The first case was that of a vegetable-seller who had left the village for Damascus on May 20th and returned to Zebdani on the 24th. He fell ill on the following morning with colic, diarrhœa, vomiting, cramps, and cyanosis, and died on the 26th. About the same time cases were reported from Douma, a few miles east of Damascus. Two men fell ill here with cholera on May 28th and died on the following day A third had suffered from vomiting and diarrhœa, but was convalescent when the other cases were reported

---

[1] The Lancet, March 4th (p. 916), July 5th (p. 39), and Nov. 22nd (p. 1414), 1902, and Jan. 31st (p. 324), and April 11th (p. 1052) 1903.

On June 6th the appearance of cholera in Ideyde, a village of 500 inhabitants, four hours north east of Damascus and in the district of Douma, was announced The first known case was that of a man from Hedjani, a village in the neighbourhood of Ideyde, who died in a tent close to the latter village on May 28th, shortly after eating a hearty meal On the same day an old man, aged 60 years, and a child, aged three years, fell ill and died On the 31st the wife of a Bedouin died, apparently from cholera, in another tent near the village On June 2nd a man and a child, aged nine years, fell ill and died suddenly Two other persons were found to have suffered from choleraic symptoms and were convalescent at the time of the inquiry.

It is clear, then, that about the last week in May and the first week in June the cholera infection had begun to spread in all directions from Damascus as a centre Villages were already infected lying from 10 to 20 miles to the east, to the west, to the north west, and to the south east A little later the disease began to advance steadily northwards On June 8th it was reported that seven cases of cholera, of which three had ended fatally, had occurred in the village of Kara in the district of Nebik, 15 hours north (or north north east) of Damascus and 12 hours south of Homs Both Nebik and Kara are on the main line of communication which runs northwards from Damascus, through Homs and Hama, and ultimately to Aleppo This, as will be shown later, has been one of the principal lines along which the present epidemic of cholera in Syria has spread, a second route of importance being the valley of the Orontes river On June 12th news was received of a suspiciously high mortality in Hama itself. Hama, or Hamath Epiphania, is a town of some size situated about the thirty-fifth parallel of latitude and rather more than half way on the road from Damascus to Aleppo The first telegram from here reported numerous deaths in a short space of time in a certain quarter of the town A sanitary inspector was sent to inquire and he definitely announced that cholera existed in the Medina quarter of Hama The outbreak here has been one of considerable severity, as shown by the following figures —

Cholera at Hama

Date	Cases	Deaths
From June 8th to 12th	?	?
,, ,, 13th ,, 19th	23	12
,, ,, 20th ,, 26th	13	7
,, ,, 27th ,, July 2nd	29	34
,, July 3rd ,, ,, 10th	41	83
,, ,, 11th ,, ,, 17th	55	56
,, ,, 18th , ,, 24th	25	35
,, , 25th ,, ,, 30th	23	26
, August 1st , ,, 7th	15	25

Although Homs lies considerably to the south of Hama and between the latter and Damascus, it was not invaded by cholera until more than a month after the disease had well established itself in Hama The first known cases occurred here on July 15th and between that date and the 31st 34 cases and 21 deaths were reported From August 1st to 7th there occurred 67 cases with 64 deaths and from August 8th to 14th as many as 146 cases and 161 deaths

In the meantime cholera was continuing more or less actively in the places already named in the near neighbourhood of Damascus and spreading to others It is impossible to find on the best maps extant the names of many of the villages to which the disease is said to have spread and it would occupy too much of your valuable space to trace in detail the course of the epidemic in each of these obscure localities It will suffice to give their names, their approximate position, and the dates where known of the first cases This I have attempted to do in the table given on next column

The course and intensity of the outbreaks of cholera in these various villages have differed greatly It must, however, be remembered that the news received from many of them has been scanty and intermittent and the mention of only a few cases from time to time in any particular village is no evidence that these are all the cases that have occurred there The date of the first case or cases in any village has rarely been given with accuracy In many instances the name of a village has only appeared in the telegrams after the disease has been present for weeks and already caused a high mortality

Name of village	Approximate position and size	Date of first cases of cholera
Cadi rand	" Three hours south of Kira (? Kara)	June 13th

Kerdjela	" Four hours south of Damascus	In July
Zahla	In the Lebanon	August 4th
Nebik	Centre of district of same name	,

Thus, for example, the first news from the village of Beytaria was that 26 persons had been attacked and that 23 died within a week From Telhab the earliest announcement was that the mortality from cholera had already reached ten per day Still more striking was the first news from Der Ali. From this village, of only 250 inhabitants, it was reported on

July 5th that 51 deaths had occurred there since June 17th, that 15 fresh cases had been declared on July 4th, and that 43 Bedouins camped near the village had also died from cholera. In like manner it was learnt from a report received at the beginning of August from the medical officer of Nebik that the disease existed in many villages that had not been mentioned in the daily telegrams and that in those which had been mentioned the mortality had been much higher than was indicated by the daily returns. The following were the figures given in this report as the totals of cases and deaths from the beginning of the epidemic to August 2nd (all the villages mentioned are in the district of Nebik):—

Name of village.	Cases.	Deaths.	Name of village.	Cases.	Deaths.
Kara	55	35	Maadania...	49	28
Derative ...	18	3	Rehebé ...	350	316
Yabroud ...	150	100	Djeroud ...	40	35
Maaloul ...	3	3	Admir ...	150	120
Aintive ...	19	16	Nasria ...	1	1
Kouteiba ...	31	18	Outrié ...	2	1

The village of Rehebé mentioned in this report had scarcely been referred to in any previous telegram and almost the first notice of the existence of the disease there was the announcement of 350 cases with 310 deaths. A similar statement is true of Admir with its sudden announcement of 150 cases and 120 deaths.

It will be gathered from these facts—and the conclusion is abundantly confirmed from other sources—that the actual course of the present epidemic, the extent of country which it has covered, and its intensity in different places are matters upon which it is impossible to speak with exactitude. All that can be said is that the greater part of the Syrian interior—or hinterland, if the word be preferred—is more or less severely affected; that the disease has steadily progressed in all directions, but particularly northwards, from Damascus; and that in all probability could the total mortality be known it would prove to be a very high figure. That the disease is an acute form of cholera is clear from the very short duration of many of the cases. The figures are far too inexact to draw any conclusions from the proportion of deaths to reported cases.

The above figures and statements refer exclusively to the epidemic in the interior of the vilayet of Syria. Recently it has spread northwards to that of Aleppo and westwards to the shores of both vilayets. The first place invaded by the disease in the Aleppo vilayet was Djisri-Shagur, 12 hours south-west of Aleppo, a town of some importance, on the Nahr-el-Asi, or ancient Orontes, river. It is not quite clear when the disease first appeared there. On July 20th it was reported that ten cases had occurred there on the previous day so that presumably it had been present there for some little time before. The course of the outbreak there follows:—

Date.	Cases.	Deaths.
to July 25th	52	18
26th ,, August 1st	83	75
,, ,, 8th	36	27
,, ,, 15th	13	10

cases of cholera occurred at Idilp, some importance, three or four hours , and between it and Aleppo. The apparently not been a serious one, the the four successive weeks numbering four, and the deaths four, four, five, and two Other villages in which cholera has appeared vilayet have been the following: Kespan and both in the district of Djisri-Shagur, first July 21st; Maharah (position not named), first July 31st; Nahli, on August 2nd; Binieh, in the at the end of July; Muara (date not named); August 12th. Cases also occurred in the Sheikhun, this village lying on the frontier two vilayets of Syria and Aleppo. From above-named places, so far as they are known, it will be seen that the cholera has advanced well on the way towards both Antioch and Aleppo, but neither of these cities has as yet become infected.

Up to July 22nd the epidemic was confined to places in the interior. On that date the first case occurred on the coast in the important port of Tripoli. On the 24th a second case occurred and for several days only occasional sporadic cases were reported, but at the beginning of August the numbers began to rise considerably and on the 4th it was reported by telegram that the inhabitants were in a state of panic, that they were leaving the city by sea and land, and that scarcely half the population remained. The last statement appears to have been an exaggeration, but it is certain that a large number of refugees have fled from Tripoli in the last fortnight—in some instances carrying the infection with them. In Tripoli itself the official figures have been as follows:—

Date.	Cases.	Deaths
From July 22nd to July 26th	2	2
,, ,, 27th ,, August 2nd	18	9
,, August 3rd ,, ,, 8th	109	61
,, ,, 9th ,, ,, 15th	109	102
On the 15th	19	15
,, 16th	14	11

Finally, two cases of cholera have been reported in th last few days from Beirût, whither the disease has bee carried by refugees from Tripoli. The first case here was tha of a sanitary guard, placed on board a sailing ship tha had arrived from Arvat, an island near Tripoli, on August 6tl He developed symptoms of cholera on the 11th. Althoug the captain of this boat denied having touched at an infecte port, it was ascertained that he had not only called at Tripo but had taken in vegetables and water there. A second cas also occurred on the 11th. The patient was a young woma who was undergoing quarantine in the lazaret at Beirût. Sh had been a passenger on a sailing ship which arrived fro Tripoli on August 7th. She died on the 13th. She is sai to have lost several relatives from cholera in Tripoli and he fellow passengers, 220 in number (on a sailing ship so sma that the crew consisted of but three men), were mostly refuge from that port.

As already stated, it is extremely difficult to form a accurate idea of the total mortality that the present epidemi has caused. The official bulletins, down to the last one published on August 17th, have reported 3182 cases and 263 deaths since March 18th. But it is very probable that wer the truth known these figures would have to be doubled o even trebled. Even from the towns and villages the information received is imperfect, while almost nothing is know of what is occurring among the Bedouin and semi-nomad population.

Constantinople, August 19th.

PS.—Since writing the above, news has been received o the appearance of cholera in Biredjik, an important tow on the Euphrates river some 60 miles north-east o Aleppo. On August 16th there were four cases and thre deaths here, on the 17th one case and one death, and o the 18th two cases. It is noteworthy that the disease ha spread so far to the north and east as Biredjik withou appearing in Aleppo first, although the latter city is in direct line between the other infected places and Biredjik It is to be feared that cholera, having reached the Euphrate river, will now spread to Armenia on the one hand and t Mesopotamia on the other.

August 20th.

MEDICINE AND THE LAW.

A Garbage-monger Imprisoned.

CASES of the exposure for sale of food unfit for huma consumption have a certain amount of similarity in thei general features. The Exeter magistrates, however, o Sept. 25th dealt with a miscreant whose offence was eve more recklessly dangerous and more crudely disgusting tha is usual. A quantity of herrings had been consigned fro Grimsby to a fish merchant at Exeter who had *refused* t accept delivery of them. The Great Western Railwa

Company officials, being naturally unwilling to keep stinking fish at their station, in order to get rid of them sold them for manure to the defendant, a man named Crawley, who thus obtained six barrels containing 2800 herrings for 4*s.*, or between four and five dozen for 1*d.* In his purchase he had as a partner another man who went at once to try to find a purchaser of the herrings as manure, during which time Crawley obtained a hand-barrow and proceeded to offer them as food in one of the poorest parts of the city. Here a sanitary inspector found him trying to sell the putrid fish as "fresh herrings" at 3*d.* per dozen, and a boy who had been engaged to help to push the barrow gave evidence that some had actually been sold. An order was obtained for the destruction of the fish and Crawley received a well-merited sentence of two months' imprisonment, being perhaps lucky in having been so early detected in his attempt upon the health of his neighbours.

Another Garbage-monger Fined.

The herrings bought wholesale at Exeter as manure and retailed by their purchaser for human food might appropriately have been followed on the dinner table by certain meat of which 27 pieces weighing 154 pounds were seized recently at Manchester. Upon the prosecution of a butcher named George Thompson of Medlock-street, Hulme, for exposing the meat for sale, evidence was given which showed that he had bought about 300 pounds on a Saturday morning at 1½*d.* per pound, that on the evening of the same day when seen by an inspector of the markets committee it was turning green and was in an advanced stage of decomposition, and that it had been cleverly disguised by being mixed with better meat, a piece of sound frozen meat being in one case found skewered to a piece of the bad meat so as to cover and to conceal it. For the defence it was said that half the meat bought had been sold and that only one customer had complained of it, that it had been a bad day for keeping meat, and that the low price was due to the wholesale traders' desire to get rid of their stocks before Sunday. The magistrates ordered Thompson to be fined £20 and costs and expressed the opinion that better supervision at the slaughter-houses on Saturday morning was needed.

Evidence before Coroners.

At an inquest held before Mr. Wynne E. Baxter upon the body of a barmaid who was stabbed at a public-house a somewhat animated discussion seems to have taken place between the coroner and the solicitor representing a person arrested for the crime who was present in custody. The dispute was not upon a point of direct medical interest but so many medical men are appointed coroners that it may be useful to call attention to it. A medical coroner may have received some legal training and yet not have had the opportunity of rendering himself familiar by practice in the courts with the points which may be raised at any moment before him. In this instance it may be observed that the coroner whose mode of putting a question was objected to said that he had had 25 years' experience in his office, to which the objecting solicitor retorted that he on his side had had 40 years' practice in advocacy. The *Daily Telegraph* thus reports the matter. The coroner asked a witness, "Have you ever heard the prisoner threaten the deceased?" "Yes." Mr. Armstrong (the solicitor): "Is not that a leading question and hardly fair to the prisoner?" The Coroner: "There is no question of leading questions in a coroner's court." Mr. Armstong: "The law of evidence applies here, I suppose?" The Coroner: "Only to a limited extent." Mr. Armstrong: "It would not be accepted where they know [illegible] to have been perfectly right [illegible] and the form in which he put his question was not an unfair one. The law of evidence only applies in a limited sense to a coroner's court in that the inquest is held, or rather conducted, by the coroner only for the purpose of ascertaining the cause of death. There are no parties before him, no one intervenes in the interest of any person suspected or otherwise except by the coroner's permission, and the coroner is responsible for the eliciting of the truth. It is a court of inquiry merely. A leading question is one which suggests its answer and is objectionable on these grounds. That is to say, an advocate is rightly not allowed by the form of his question to put into the mouth of his own witness the answer which he desires to obtain. The coroner is not an advocate, nor is he a judge holding even the balance between two advocates; he is endeavouring to get at the facts in the interests of the public and very often has but little to help him in so doing. Consequently he not only may, but sometimes must, put questions in a form which would not be permitted in the case of a prosecuting counsel upholding a particular theory with regard to a crime as against that propounded by the defence. Moreover, the question put by Mr. Wynne Baxter was only to a very small extent a leading question. It suggested the idea of threats but there was nothing in the form of it to show that a particular answer was expected and the reply might have been "yes" or "no." Had he asked "Have you *not* heard the prisoner threaten the deceased?" he would clearly have suggested a response in the affirmative. Had he said, putting the words actually used into the witness's mouth, "Did you once hear the prisoner say 'I will put her light out'?" he would have caused the answer "Yes" to cover a detailed statement of matters with regard to which the witness should have given evidence spontaneously and to have done so would have interfered with the fairness of the inquiry. It is true that Mr. Wynne Baxter might have said to the witness "Have you ever heard the prisoner speak of the deceased?" and on obtaining the answer "Yes" might have followed up the first question by asking "In what terms did he do so?" and so on until he arrived at the words actually used. To do this would be open to no objection from the advocate appearing for a suspected person but under such conditions the coroner might not find it easy to get through his work in the time at his disposal and might also find it very much more difficult than it now is to arrive at any conclusion at all. The accused person is protected from any possible injustice by the fact that at his ultimate trial, if he be committed, a stricter practice prevails than that of the coroner's court.

MEDICAL SCHOOL DINNERS.

The Middlesex Hospital.—Adhering strictly to precedent the past and present students of the Middlesex Hospital and their friends assembled on Oct. 1st at the Trocadéro Restaurant to celebrate the commencement of the academic year. There was a good attendance, 141 sitting down to dinner, under the chairmanship of Dr. William Pasteur, physician to the hospital. The guest of the evening, the Hon. Mr. Justice Wills, had presided during the afternoon at the opening ceremony in the medical school, distributing the scholarships and prize swith much geniality and interest. Lord Sandhurst, K.C.S.I., having resumed his old position in the direction of affairs as chairman of the weekly board, was also present with other members of the governing body and of the consulting and active staff. After the royal toasts had been duly honoured that of "The Services" was proposed by Sir Richard Douglas Powell who referred to numerous officers in all branches of the public service who had received their medical education at the Middlesex Hospital. Lieutenant-Colonel M. W. H. Russell responded, alluding to the services of the medical department in the field during the recent war and acknowledging the appreciation of the *personnel* even if criticism had fallen on the former system of the Royal Army Medical Corps which had recently undergone extensive modifications and reforms. The toast of "The Middlesex Hospital and the Medical School" was then given by the chairman who dwelt upon the steady progress of both and referred to the recent additions and improvements which rendered the school not only complete in all essentials but placed it in the first rank in research and laboratory equipment. Lord Sandhurst replied on behalf of the hospital, mentioning his unbroken association with medical organisation, since the interval between his former and present tenure of the chairmanship had been devoted to the Presidency of Bombay in the period of plague and famine, where he had still further proof of the devotion and sympathy of the members of the medical profession. Mr. John Murray, the Dean, spoke on behalf of the medical school the full achievement of which he had given in the afternoon. The health of the past and present students was proposed by Dr. Sidney Coupland in an excellent speech full of reminiscences of an earlier phase of hospital work and was replied to by Dr. Edward Norton and Mr. W. A. Rees, representing respectively the former and present pupils of the school. The health of the visitors was proposed by Mr. Stephen Paget in a humorous and appropriate speech and was responded to by the Hon. Mr. Justice

Wills and by Mr. Wilhelm Ganz, under whose direction, with the assistance of Mr. Bovett, Mr. Hugh Peyton, and Mr. Charles Deacon, a most enjoyable musical programme was given. With the toast of "The Chairman," proposed by Mr. A. Pearce Gould and feelingly acknowledged, a most enjoyable gathering terminated shortly after 11 P.M.

Charing Cross Hospital.—Mr. C. Carter Braine presided on Oct. 1st at the annual dinner of the past and present students of the Charing Cross Hospital which took place at the Hotel Cecil, London. The toast of "The Hospital and Medical School" was given by Mr. Braine who spoke of the loss which the institution had sustained by the retirement of Dr. T. H. Green from the medical staff. He said that the name of "Tommy Green" was known throughout the entire medical world in connexion with clinical teaching. Although the medical school of Charing Cross Hospital must be always a small one they must make up for the paucity in numbers by the quality of the men. Mr. Braine made a short speech because, he said, that as an anæsthetist it was his duty to keep his eyes and ears open and his mouth shut. Dr. F. W. Mott in responding described the way in which Dr. Green's book on Pathology had stimulated him as well as others in their work. Mr. H. F. Waterhouse then gave the toast of "The Visitors" and told his audience how he had been charged by Sir Charles Wyndham to express his regret at his unavoidable absence from the dinner. Sir Charles Wyndham had also requested him to convey to the students of the hospital an invitation to come on any date they might fix to his theatre where he would be glad to welcome them. A telegram accepting the invitation was duly despatched to Sir Charles Wyndham. Mr. P. J. Freyer replied for the visitors. Mr. Stanley Boyd in a neat speech proposed the toast of "The Chairman's Health" and an enjoyable dinner was brought to a close by a very hearty acknowledgment being accorded to the two honorary secretaries, Mr. G. S. Welham and Mr. Sidney Boyd, for the manner in which they had carried out the duties of their office.

St. Bartholomew's Hospital.—The annual dinner took place on Oct. 1st in the great hall of the hospital. Mr. W. Bruce Clarke occupied the chair and 183 persons were present. In proposing the toast of the evening the chairman congratulated the hospital on having passed through the late crisis and referred warmly to the good feeling and close connexion between the hospital and the school. Mr. Alderman Alliston responded, the treasurer being unavoidably absent. He spoke heartily and cheerfully of the future and in behalf of the lay administration thanked the chairman for his cordial expressions of loyalty and goodwill. The toast of "The Guests" was proposed by Dr. S. J. Gee, who expressed the hearty desire of the school to contribute toward the success of the University of London. The Principal of the University, Sir A. W. Rücker, in responding, referred warmly to the energy and capacity shown by Mr. H. T. Butlin as Dean of the Faculty of Medicine and gave some remarkable figures to illustrate the increase in the number of undergraduates. Mr. Butlin then proposed the health of the chairman and with the usual vote of thanks to the secretary the dinner ended.

St. George's Hospital.—There was a record attendance at the annual dinner of the medical school held on Oct. 1st in the Whitehall Rooms of the Hotel Métropole. The chair was occupied by Dr. T. Clifford Allbutt, Regius Professor of Physic at the University of Cambridge, who in proposing the toast of the evening expressed his conviction that the time had come when more research work must be accomplished at the great hospitals of the metropolis. The ordinary clinical material should be used not only for the benefit of the patients attending the hospitals but for the purpose of guiding scientific thought and enriching medical science. In this way it would be possible to make medical discoveries which would inevitably promote the well-being of the general public. To their infinite credit the governors of St. George's Hospital had approved of the principle that the medical men who gave their entire time to the services of the hospital in positions such as that of medical registrar should do so free from financial embarrassment. That was a new departure and they were all agreed that it was eminently calculated to advance English medicine. The toast was responded to by the dean, Dr. Arthur Latham, who said he was glad to state that St. George's Medical School still stood at Hyde Park Corner. Success had attended their efforts in every department during the past year and the prospects of continued success were never greater. As Professor Allbutt had said, owing to the enlightened policy of the governors, St. George's Hospital Medical School was now in a position to offer greater facilities to men who wished to devote themselves to medical and surgical research after obtaining their qualifications than any other hospital in England. A number of other toasts were honoured. Professor G. Sims Woodhead, responding for the toast of "The Guests," said that he esteemed it a great honour to be allowed to dine with St. George's men. He congratulated the school on its well-deserved success and on its virility. During the evening it was suggested that a hearty greeting should be sent to Dr. E. A. Wilson who was icebound in the Antarctic circle on board the *Discovery*. The suggestion met with the approval of the chairman and the enthusiastic indorsement of everybody attending the banquet.

University College Hospital.—Dr. Walter Rigden presided on Oct. 5th at the annual dinner of the old and present students of University College Hospital, which was held at the Hotel Cecil. The first toast after that of "The King" was proposed by Dr. Frederick T. Roberts and was that of "The President of the Royal College of Surgeons of England." Dr. Roberts explained that Mr. John Tweedy, the President, had been called away from London and was unable to be present. He congratulated the Royal College of Surgeons of England on its choice and was glad to see it widening its electoral field by selecting for the first time an ophthalmologist to the honourable post of president. Dr. Rigden proposed "The Medical School and University College Hospital," which was responded to by the dean of the faculty of medicine, Dr. Sidney H. C. Martin, who discussed the question of proper endowment for the prosecution of higher research studies. The majority of men found it so hard to make a living that they had no time for research. Well-paid professorships were required of such value that men could live on them and then men would be found to investigate the processes of disease. Mr. Christopher Heath, in a eulogistic speech, proposed the health of the chairman, which Dr. Rigden acknowledged. An enjoyable evening was concluded by a speech from Dr. E. Rayner of Stockport in praise of the successful efforts of the two honorary secretaries for the dinner, Mr. Raymond Johnson and Dr. H. B. Shaw.

King's College Hospital.—The old students of King's College Hospital held their annual dinner at the Hotel Cecil on Oct. 1st. For the last few years this gathering has been more fully recognised as a means of reviving old friendships of student days and on the present occasion the average of attendances was well maintained. Dr. C. H. Allfrey of St. Leonards-on-Sea, a past student whose record dates back to the early "sixties," was in the chair and that his selection for the post was a happy one was evidenced by the number of personal friends and contemporaries who were present to support him and by the admirable manner in which he presided. The Rev. A. C. Headlam, the recently appointed principal of the college, was an honoured guest, and Sir John A. Cockburn, K.C.M.G., himself a former student, who had delivered the address and distributed the prizes at the formal opening of the medical session in the afternoon, also attended. The past members of the staff were represented by Dr. I. Burney Yeo and the majority of the existing staff were present in person. Lieutenant Colonel A. T. Sloggett, C M.G., R.A.M.C., responded to the toast of "The Services," proposed by Mr. W. Watson Cheyne, C.B. The toast of the evening, "King's College and King's College Hospital," was proposed by the chairman and responded to by the Rev. A. C. Headlam. Mr. Reid, Mr. Hughes, Mr. Turtle, and Mr. Dunkerton contributed an excellent selection of music. Greetings were exchanged with the Charing Cross Hospital dinner, which was being held in the same building, and altogether a very enjoyable evening was spent.

St. Mary's Hospital.—The annual dinner of the past and present students was held in the Whitehall Rooms of the Hôtel Métropole on Oct. 2nd, Dr. R. Farquharson, M.P., being in the chair. There was a good attendance, 175 being present, and the guests included Mr. Henry Harben, chairman of the hospital board, Sir A. W. Rücker Principal of the University of London, and Mr. F. G Hallett. The loyal toasts proposed by the chairman were duly honoured. The chairman in proposing "Prosperity to St. Mary's Hospital Medical School" said that the toast recalled old memories to him as a physician and former student of the hospital The progress of St. Mary's Hospital during the last 40 years had been extraordinary, and he attributed this to the strength of its staff and the high traditions of work and duty which it had established He recalled the services of the late Mr Samuel Lane and Mr James Lane to whom the hospital owed so much, and congratulated the school on retaining the services of the third generation in the person of Mr Ernest Lane The Dean, in replying for the teaching staff, referred to the growing numbers and increasing influence of their past students in every department of professional work. Captain Rogers, I M S, replied for the past students and Mr J R Rous for the present students Mr Page gave the toast of "Our Guests," coupled with the names of Mr Harben and Sir Arthur Rücker Sir Arthur Rücker, in replying, congratulated the school on the increase of its students this session He was glad to say that there had been a general increase in the university entries In June there were 700 more candidates and in September 400 more for matriculation than in the previous year The work of coördination had received an important stimulus from the work of Dr Waller in relation to the higher teaching in physiology, and similar advances had now been made in biology and in the faculty of arts Sir [illegible] the health of the chairman who [illegible] y years ago he had severed his [illegible] Hospital with great regret, and that was only atoned for by anything he might have done to promote the welfare of the medical profession

Looking Back.

FROM

THE LANCET, *SATURDAY*, OCT. 8, 1825.

THE INTRODUCTORY ANATOMICAL LECTURES DELIVERED IN LONDON ON THE FIRST OF OCTOBER, 1825

WE this week present out readers with the introductory addresses of all the anatomical lecturers of London, with the exception of those of Mr Carpue and Mr Mayo[1] The former of whom is not in the habit of delivering an introductory lecture, which, to use his own expression, he considers a *flash in the pan*, and the latter called at our office for the express purpose of stating that he objected to the publication of his lecture We did not attempt to inquire into the grounds of Mr Mayo's objection, but we are disposed to give him credit for having exercised a sound judgment. Posterity may, indeed, suffer from Mr Mayo's resolution, but as cruelty to posterity is not yet made an offence by the humane Mr Richard Martin we know not how to avert the threatened calamity, if Mr Mayo chooses to continue inexorable

Mr Mayo is a private lecturer, and he has a right therefore to exercise his own discretion with respect to the publication of a private lecture, but our friend Mr ABERNETHY stands, we maintain, in a very different situation, and we have no scruple, therefore, in publishing *his* introductory lecture in order to complete the series even though he may on this, as on former occasions, be inclined to recalcitrate As a Hospital lecturer, independently of the monopoly which he has procured for himself by the College Bye-law, he must abide by the consequences of his situation, we are anxious to bring this question to a fresh hearing, we are prepared to meet our friend, even though he should think fit to invade the retirement of Lord ELDON for a fresh injunction Mild and gentle as we know Mr Abernethy to be in all other respects, as a public Hospital lecturer we consider him as much *feræ naturæ* as the partridges which the Lord Chancellor, not having the fear of Richard Martin before his eyes is now bagging at Encombe

The order in which the lectures stand, has been adopted with a view to our convenience, and is by no means to be considered as a test of their respective merits

ASYLUM REPORTS.

Dundee Royal Asylum (Annual Report for 1902).—The average number of patients resident during the year was 436, comprising 176 males and 260 females The admissions during the year amounted to 201—viz 87 males and 114 females Of these 155 were first admissions Dr James Rorie, the medical superintendent, states in his report that the advanced age of many on admission still continues to be a prominent feature, one patient being 67, one 69, three 70, one 72 one 73 one 75, and one 81 years old Of the admissions 28 were paupers from other asylums The physical condition of the patients on admission has been very similar to that of former years The number of patients discharged as recovered during the year amounted to 59—viz, 25 males and 34 females, or 13 5 per cent of the average number resident The deaths during the year amounted to 40, or 9 1 per cent as calculated on the same basis Of the deaths three each were due to cardiac disease and cerebral paralysis, four to pulmonary tuberculosis five to senile decay, ten to general paralysis of the insane, and the rest to other causes "The principal feature in the mortality" says Dr Rorie, "is again the large number of deaths due to general paralysis, this and other organic brain diseases accounting for 55 per cent of the total number of deaths" The mortality has been chiefly amongst those recently admitted One patient, however, had been a resident in the asylum for over 54 years "For a considerable time he had been out on parole and had practically complete freedom Being in possession of a small annuity he was in the habit of taking his sister with him to various parts of the country for a fortnight's holiday yearly The delusions from which he suffered were of a harmless nature towards the end of his career but remained vivid to the last." In consequence of the recent serious accident by fire at Colney Hatch Asylum, London, the arrangements for extinguishing fire have been carefully inspected by the superintendent of the Dundee fire brigade and found equal to meet all contingencies The Commissioners in Lunacy state in their report that the patients were found to be in a satisfactory condition as regards clothing and personal neatness, that the care and treatment of the sick and of newly admitted patients continued to be skilful and efficient that all parts of the institution were in good order, and that the medical case books and registers were found to be accurately and well kept. The committee of management states in its report that arrangements are in progress for the purchase of a property and buildings at Westergreen to increase the capacity of the asylum The conditions of sale and purchase require the sanction of Parliament and a Bill authorising the purchase has passed through both Houses and only awaits the Royal Assent

Lincoln County Asylum, Kesteven (Annual Report for 1902).—The asylum was opened in June, 1902 The average number of patients resident during the year was 146 comprising 64 males and 82 females The admissions during the year amounted to 93—viz, 25 males and 68 females Of these 40 were first admissions Dr J A. Ewan, the medical superintendent states in his report that the chief event of the year was the removal of the patients accommodated at the temporary asylum at Grantham to the present building, which was accomplished without mishap on June 20th, 1902 Of the admissions 40 were brought directly from the unions of the county of Lincoln Of these "a large proportion consisted of the restless old and feeble, or paralysed, who undoubtedly require care and nursing, and for this class of case such attention at present, in country districts at least, can seemingly only be obtained in a lunatic asylum, although, perhaps, the workhouses would be a more fitting shelter" Only about 25 per cent of those admitted were deemed curable The number of patients discharged as recovered during the year amounted to eight—viz, four males and four females or 5 4 per cent of the average number resident. The deaths during the year amounted to 17—viz, 11 males and six females, or 11 6 per cent as calculated on the same basis Of the deaths two each were due to epilepsy and bronchitis three to general paralysis of the insane, four to cardiac disease, and the rest to other causes "It is satisfactory to note," says Dr Ewan, "that tubercular disease was again absent from the death list. The male wards are still in an unfinished condition but all those on the female side have been coated with duresco and five out of the seven are in full occupation One ward has been set aside for paying patients and it is intended to receive at the lowest possible remuneration consistent with a more liberal diet and extra nursing those whose means do not permit of their being sent to one of the more expensive private asylums. The grounds are already fairly well planted with trees and shrubs; the farm and orchard are not yet fully under cultivation, but it has been possible to grow enough potatoes, turnips, oats, and hay for the requirements of the institution. The weekly charge of maintenance has remained at 12*s.* 10*d.* per patient. The Commissioners in Lunacy state in their report that the asylum is designed to accommodate in the first instance 420, and ultimately, by the addition of two more blocks, 600 patients. The design, structure, and workmanship displayed in the building seemed to be excellent and the occupied wards were suitably furnished. They add that the condition of the patients was satisfactory and that the medical case books were properly kept. The committee of management states in its report that the making of roads and the planting and laying out of the grounds have been nearly completed and that the building is lighted throughout with electricity.

---

[1] The addresses reported are by the following lecturers:—Mr Abernethy, Theatre of Anatomy St Bartholomew's Hospital Mr Brookes Theatre of Anatomy [illegible] Cooper, New Theatre Guy's Hospit[illegible] London Hospital Mr Grainger The[illegible] Maze Pond Mr Sleigh Theatre [illegible] Grosvenor square, Mr Dermott New [illegible] Windmill street Golden square, M[illegible] Anatomy, Great Windmill street and Mr Green Theatre St Thomas's Hospital

Earlswood Asylum, Surrey (Annual Report for 1902).—The average number of patients resident during the year was 515, comprising 336 males and 179 females. The admissions during the year amounted to 56—viz., 38 males and 18 females. Of these 49 were first admissions. Dr. Charles Caldecott, the medical superintendent, states in his report that 23 out of the 56 admissions showed a history of insanity or idiocy in the parents, while in 22 cases the cause of the illness was attributed to troubles connected with pregnancy and parturition. "It is gratifying," adds Dr. Caldecott, "to record a larger number of younger cases, many of whom already give promise of progress in the school or shop; on the other hand, a few must be classed as 'custodial or untrainable' and one or two will be chronic infirmary cases." The number of patients discharged as relieved during the year amounted to 34, or 6·6 per cent. of the average number resident. The deaths during the year amounted to 13—viz., six males and seven females, or 2·5 per cent. as calculated on the same basis. Of the deaths, one each was due to apoplexy, renal disease, intestinal obstruction, and influenza, three were due to epilepsy, and six to pulmonary and other forms of tuberculosis. Post-mortem examination was made in ten cases of death, or 77 per cent. The low death-rate is "a record for 44 years, with one exception, and appears little short of marvellous when allowance is made for the fact that six patients have been in residence over 50 years, 44 patients over 40 years, and no less than 102 [patients] over 30 years." 61 males and 31 females have had 7974 fits during the year. The general health of the patients has been good during the year and minor ailments such as coughs, colds, and chilblains have been less numerous than formerly, a fact attributable to the improved condition of the atmosphere of the buildings as a result of recent alterations in the lighting, heating, ventilating, and sanitary arrangements. The reports of the head mistress and head master of the schools and workshops and of the house steward state that good progress is being made by the patients who attend as pupils and workers in these two departments. The Commissioners in Lunacy state in their report that the large proportion of deaths from tuberculosis "emphasises the importance of some separate provision being made for the treatment of this class of disease which is now recognised as of an infectious character." All parts of the institution were found to be in good order at the visit, the rooms were bright and cheerful, the beds and bedding were in good condition, and signs of progress were visible everywhere. The committee of management states in its report that steps are being taken to increase and to improve the means of exit in case of fire at an estimated cost of £2000.

PUBLIC VACCINATORS AND THE VACCINATION ORDER OF 1898.—The departmental committee appointed by the President of the Local Government Board to inquire and to report with regard to the payments made to public vaccinators and vaccination officers under the Vaccination Order, 1898, heard on Oct. 1st the evidence of Mr. Joseph Brown, president of the Association of Poor-Law Unions in England and Wales, Mr. F. W. Dimbleby, senior vice-president of the association, and Mr. A. F. Vulliamy, a member of the association and clerk to the Ipswich board of guardians. The committee has already heard the evidence of the official witness, Mr. W. W. Conolly, principal clerk of the public health department of the Local Government Board

Public Health and Poor Law.

LOCAL GOVERNMENT BOARD.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

Southampton Port Sanitary District.—The port of Southampton has within recent years increased enormously in importance and such expansion has been accelerated very materially by the fact that this port is now almost the sole centre of embarkation and disembarkation of troops leaving and returning to this country. Hence it comes about that the proper administration in a sanitary sense of the port of Southampton is a national matter. Some idea of the additional work which the late war in South Africa imposed upon the Southampton port sanitary authorities may be gathered from the fact that during 1902 no fewer than 472,927 persons arrived in Southampton by sea, this number being an increase of 123,000 over that of 1901. The efficient manner in which the duties of the port sanitary officials were performed may be inferred from the fact that no case of plague or cholera was introduced into the town during the year although a large number of vessels arrived from plague- and cholera-infected ports. As regards the introduction of non-exotic infectious diseases it is interesting to note that during 1902 as many as 127 cases of enteric fever were landed at Southampton and removed to hospital, and among other cases of illness which were landed we notice 145 of malaria, 16 of dysentery, 65 of venereal diseases, and 107 of pneumonia. Only one case of yellow fever was reported to have occurred on board a vessel bound for Southampton and this case was landed at Buenos Ayres. Of the 138 transports which arrived in Southampton during the year under review 118 were from South Africa and 12 were from Bombay. Of the total 4530 vessels of all kinds which arrived 4007 were British and 258 were German. The amount of work involved in dealing with all these transports and other vessels shows that the post of medical officer of health, which is at present filled by Mr. R. E. Lauder, is very far from a sinecure.

Metropolitan Borough of Poplar.—Mr. F. W. Alexander states in his current annual report that 14 cases of enteric fever were "directly traceable" to the eating of shell-fish, but in only two of these cases is any statement supplied as to the dates at which the shell-fish were eaten. The fact that in several instances the shell-fish (cockles) had come from Southend is presumptive evidence that the cockles were likely to have caused the disease, but in the absence of the dates even this is perhaps rather straining the logical position. One patient is stated to have eaten oysters a month previously and another had eaten cockles from Margate. Doubtless Mr. Alexander possesses all the needful information to incriminate both the cockles and the oysters but it is desirable, when possible, to furnish the dates as well as the sources of the shell-fish. As Dr. J. T. C. Nash of Southend has shown, cockles were in all probability instrumental in causing much enteric fever at Southend but it does not follow that everyone who subsequently develops enteric fever owes the attack to having eaten Southend cockles. Attention has been given in Poplar to the presence of preservatives in milk and during 1902 13·6 per cent. of the samples of milk examined contained either formalin or boric acid. The percentage of formalin present amounted to 0·02, while the amount of boric acid ranged from 0·2 to 0·01 per cent. In butter the boric acid ranged from 0·04 to 0·8 per cent.

The Port Sanitary District of Manchester.—The total tonnage of shipping borne to Manchester upon the waters of the Manchester Ship Canal is increasing year by year and with it there is, of course, also an increase in the amount of sickness introduced into the port. The work of the port sanitary officials has also been increased by virtue of the fact that the port sanitary authority has taken over the work of inspecting the canal boats within the port limits. When it is borne in mind that there are wharves and lay-byes where vessels can discharge their cargo throughout the 35 miles of the canal it is clear that the time of one medical officer of health and two inspectors must be often severely taxed. During 1902 there were 140 cases of sickness dealt with but only a small portion of these belonged to the communicable diseases concerning which precautions are taken in this country. Dr. A. M. N. Pringle, the medical officer of health, raises a very important general question in his

report as regards the sanitary condition of ships, a matter which should, in our view, receive the attention of the Local Government Board The construction of new vessels is governed entirely by the Merchant Shipping Act, under the provisions of which it devolves upon the Board of Trade surveyors to examine a ship and to give a certificate that the vessel complies with the requirements of the Board of Trade These surveyors have practically no training in sanitary matters and they are unable to exercise an adequate influence over the construction of vessels in a sanitary sense Now Dr Pringle alleges that it is by no means infrequent to find glaring contraventions of the Merchant Shipping Act on perfectly new ships The surveyor's attention is, perhaps naturally, turned more particularly towards the question of the seaworthiness of the vessel and he pays but small regard to its sanitary condition Although there is a minimum cubic space provided by the Merchant Shipping Act for each member of the crew, it is, we fear, true that the general sanitary condition of the forecastle is by no means sufficiently attended to and there is obviously a difficulty in insisting upon alterations in the case of a new ship provided with a quite recent certificate from the Board of Trade surveyor All those who are at all familiar with the sanitary condition of vessels will, we think, agree with Dr Pringle that there is need for reform and that this reform should take the shape of submitting the plans of new vessels to the port sanitary officials There should in a word, be just the same control over the construction of ships by port sanitary authorities as obtains on land in the case of new houses Dr Pringle's report furnishes a table which affords an admirable object lesson of the point which he urges Among the defects in connexion with the lighting of crews' quarters we find 78 cases in which the insuffici
window accommodation, a
94 cases were due to
apparatus provided On
during 1902 no fewer than 870 exhibited insanitary conditions in some form or other

Croydon County Borough —Dr H. Meredith Richards has been instrumental in introducing a system of voluntary notification of pulmonary tuberculosis into Croydon But he wishes it to be understood that he holds no extremist views as to the "infectiousness" of the disease We are glad to see that he agrees largely with Sir Hugh Beevor and holds with the views which we have recently given expression to in a leading article in our columns As Dr Richards remarks, it is a misuse of language to speak of the infectiousness of tuberculosis as in any way comparable with that of measles or small pox, and all epidemiologists will agree with him that the truest progress is to be made in promoting generally the resistance of the individual The system which is in vogue in Croydon of the notification of diseases which occur among school children should lead to valuable results, more especially with respect to those cases which are notified under the heading of "sore throat During 1902 there were 358 cases of ringworm and 360 cases of chicken pox notified It is to be hoped that the corporation of Croydon, now that it has become the educational authority, will under the advice of Dr Richards, set an example in the direction of thoroughly up to date school buildings and in the periodical examination of school children, not only as regards communicable diseases but as to the condition of their special senses and their general physical condition As Dr Richards observes, "most brilliant scholastic achievements would be dearly bought at the expense of permanently impaired health '

VITAL STATISTICS

HEALTH OF ENGLISH TOWNS

IN 76 of the largest English towns 8067 births and 4424 deaths were registered during the week ending Oct 3rd The annual rate of mortality in these towns, which had been 15 8, 16 5, and 16 3 per 1000 in the three preceding weeks, further declined last week to 15 3 per 1000 In London the death rate was 14 1 per 1000, while it averaged 15 9 per 1000 in the 75 other large towns The lowest death rates in these towns were 6 3 in Handsworth 7 6 in East Ham, 7 8 in West Bromwich, 7 9 in Aston Manor, 8 2 in Willesden, 8 6 in Hornsey, 8 7 in Northampton, and 9 0 in King's Norton and in Wallasey, and the highest rates 20 2 in Swansea, 20 3 in Middlesbrough, 20 9 in West Hartlepool, 21 0 in Wigan and in Salford, 21 9 in Rotherham, 22 1 in Great Yarmouth, 22 6 in Merthyr Tydfil, and 25 1 in Newcastle on Tyne The 4424 deaths in these towns last week included 697 which were referred to the principal infectious diseases, against 924, 918, and 752 in the three preceding weeks, of these 697 deaths, 495 were referred to diarrhœa, 52 to diphtheria, 41 to "fever" (principally enteric), 38 to measles, 38 to whooping cough, 31 to scarlet fever, and two to small pox. No death from any of these principal infectious diseases was registered last week in Tottenham, Barrow-in Furness, or Tynemouth; among the other towns they caused the lowest death rates in Hornsey, Willesden, Brighton, King's Norton, Grimsby, Rochdale, and Halifax and the highest rate in Walthamstow, Southampton Great Yarmouth, Hanley, Coventry, Bootle, Burnley, Middlesbrough, and Merthyr Tydfil. The greatest proportional mortality from measles occurred in Warrington, from diphtheria in Reading, from whooping cough in York and Rhondda, from "fever" in Merthyr Tydfil, and from diarrhœa in Walthamstow, Southampton, Great Yarmouth Hanley, Coventry, Bootle, Burnley, Middlesbrough, and Merthyr Tydfil The mortality from scarlet fever showed no marked excess in any of the large towns One death from small pox was recorded last week in Hanley and one in Newcastle on Tyne, but none in any other of the 76 large towns The number of small pox patients remaining under treatment in the Metropolitan Asylums hospitals, which had been 46, 41, and 29 on the three preceding Saturdays, had further declined to 21 on Saturday last, the 3rd inst, one new case was admitted during last week, against nine, seven, and one in the three preceding weeks The number of scarlet fever cases in these hospitals and in the London Fever Hospital at the end of last week was 1877, against 1772, 1803, and 1886 at the
were admitted
ie three pre-
the respira
tory organs in London, which had been 122, 128, and 134 in the three preceding weeks, further rose last week to 161, and were 12 above the number in the corresponding period of last year The causes of 42, or 0 9 per cent, of the deaths in the 76 large towns last week were not certified either by a registered medical practitioner or by a coroner All the causes of death were duly certified in West Ham, Salford, Leeds Hull, Newcastle on Tyne, and in 54 other smaller towns, the largest proportions of uncertified deaths were registered in Birmingham, Liverpool, Manchester, Sheffield, Middlesborough, and Gateshead

HEALTH OF SCOTCH TOWNS

The annual rate of mortality in eight of the principal Scotch towns, which had been 14 4, 16 1, and 16 8 per 1000 in the three preceding weeks, further rose to 17 3 per 1000 during the week ending Oct 3rd, and was 2 0 per 1000 above the mean rate during the same period in the 76 large English towns The rates in the eight Scotch towns ranged from 13 7 in Leith and 14 3 in Greenock, to 18 6 in Perth and 18 8 in Dundee The 566 deaths in these towns included 42 which were referred to diarrhœa, seven to whooping cough, six to "fever," four to measles, four to diphtheria, and two to scarlet fever, but not one to small pox In all, 65 deaths resulted from these principal infectious diseases last week, against 77, 51 and 77 in the three preceding weeks These 65 deaths were equal to an annual rate of 2 0 per 1000, which was 0 4 per 1000 below the mean rate last week from the same diseases in the 76 large English towns The fatal cases of diarrhœa, which had been 52 19, and 44 in the three preceding weeks, declined again last week to 42 of which 21 occurred in Glasgow, five in Edinburgh, five in Dundee, five in Leith, two in Aberdeen, and two in Greenock. The deaths from whooping cough, which had been nine, 10, and nine in the three preceding weeks, further declined to seven last week, and included five in Glasgow and two in Edinburgh The deaths referred to different forms of "fever," which had been seven, five, and seven in the three preceding weeks, decreased last week to six, of which four were registered in Glasgow The fatal cases of measles which had been eight and five in the two preceding weeks, further declined to four last week and included three in Glasgow The deaths from diphtheria, which had been two, six, and eight in the three preceding weeks, declined again last week to four, of which three occurred in Edinburgh. The deaths referred to diseases of the respiratory organs in these towns, which had been 52, 71, and 84 in the three preceding weeks, further rose last week to 88, and were slightly in excess of the number in the corresponding period of last year. The causes of 26, or nearly 5 per cent., of the deaths registered in these eight towns last week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 18·7, 19·5, and 21·7 per 1000 in the three preceding weeks, declined again to 18·3 per 1000 during the week ending Oct. 3rd. During the 13 weeks ending on that date the death-rate averaged 18·9 per 1000, the rates during the same period being 14·1 in London and 14·5 in Edinburgh. The 133 deaths of persons belonging to Dublin registered during the week under notice showed a decline of 25 from the number in the preceding week and included 5 which were referred to the principal infectious diseases, against 10, 17, and 16 in the three preceding weeks; of these, two resulted from "fever" and three from diarrhœa, but not one from small-pox, measles, scarlet fever, diphtheria, or whooping-cough. These five deaths were equal to an annual rate of 0·7 per 1000, the death-rates from the principal infectious diseases during the same period being 2·2 in London and 1·9 in Edinburgh. The deaths from diarrhœa, which had been seven, five, and 14 in the three preceding weeks, declined again to three last week. The fatal cases of "fever," which had been one, three, and one in the three preceding weeks, rose again last week to two. The 133 deaths in Dublin last week included 33 of children under one year of age and 34 of persons aged 60 years and upwards; the deaths both of infants and of elderly persons showed a marked decline from the numbers in the preceding week. Six inquest cases and five deaths from violence were registered, and 42, or more than a third, of the deaths occurred in public institutions. The causes of five, or nearly 4 per cent., of the deaths registered in Dublin last week were not certified.

THE SERVICES.

INDIAN MEDICAL SERVICE.

THE subject of the salaries of officers in civil employ, referred to in paragraph 19 of the Memorandum of October, 1903, is now under the consideration of the Government of India.

ROYAL ARMY MEDICAL CORPS.

Surgeon-General W. J Fawcett, Principal Medical Officer, 3rd Army Corps, is taken on to the establishment of his rank, A.M.S., in consequence of Sir William Wilson, K.C.M.G., having attained the age limit and being retained as a supernumerary. Captain H. N. Dunn has been selected for special employment with the Abyssinian contingent in Somaliland and is ordered to embark for duty at once. Surgeon-Captain R. H. Luce, A M R., has assumed medical charge of the station hospital and troops, Derby.

Lieutenant-Colonel A. Baird retires on retired pay (dated Oct. 3rd, 1903); Lieutenant-Colonel R D. Donaldson retires on retired pay (dated Oct. 3rd, 1903); Captain A. C. Lupton, from half-pay, to be Captain, with precedence next below M. M. Lowsley (dated Sept. 5th, 1903); Lieutenant D. D. Paton is seconded under the provisions of Article 349 of the Pay Warrant (dated Oct. 1st, 1903); Lieutenant-Colonel R. W. Mapleton retires on retired pay (dated Oct. 7th, 1903); Captain A. F. Heaton retires from the service, receiving a gratuity (dated Oct. 7th, 1903).

VOLUNTEER CORPS.

Royal Garrison Artillery (Volunteers): 3rd Kent (Royal Arsenal): Surgeon-Major A. H Robinson to be Surgeon-Lieutenant-Colonel (dated Oct. 3rd, 1903). 1st Monmouthshire: Surgeon-Captain W. E. James resigns his commission (dated Oct. 3rd, 1903).

Royal Engineers (Volunteers): 1st Gloucestershire: Surgeon-Captain G. H. Ward-Humphreys resigns his commission (dated Oct. 3rd, 1903).

PRIZE DAY AT HASLAR.

The session for the surgeons of the Royal Navy under special instruction at the Royal Naval Hospital, Haslar, terminated on Sept. 30th when the prizes were presented by Admiral J. Durnford, C B., D S.O., one of the Lords of the Admiralty. The Director-General of the Medical Department of the Royal Navy, Sir Henry F. Norbury, K.C.B., was also present. The following is a list of the marks gained by the respective officers:—

Name.	Marks.	Name.	Marks.
A. W. Iredell	4238	E. S. Wilkinson	3128
F. C. Robinson	3993	R. Kennedy	3053
C. E. C. Child...	3892	E. A. G. Wilkinson ...	3039
M. T. Malo	3826	J. H. L. Page	3017
C. H. Dawe	3661	W. E. Ormsby...	2984
R. Thompson	3620	J. J. H. Rooney	2979
W. K. D. Breton	3545	A. F. Fleming...	2678

The prizes were awarded to F. C. Robinson (gold medal), A. W. Iredell (silver medal and books), and C. E. C. Child (microscope). Sir Henry Norbury, after reading the report of the professors of the medical school, complimented the officers who had been under instruction on their marked application to their studies and their general good conduct which reflected very great credit on them all. He deplored the untimely death of one of their number, Surgeon Illingworth, which had taken place during the session, and then referred to the honour which was being done to them by the presence of Admiral Durnford who had kindly consented to give away the prizes, an officer to whom the Naval Medical Department owed a deep debt of gratitude. He had during his term of office as a Lord of the Admiralty worked hard to understand its requirements and had made untiring and successful efforts for its improvement and he was sure that they were all pleased to see him there that day. Admiral Durnford then distributed the prizes. He said that the report which had been read was a most satisfactory one and two things at once struck him, first, the credit that reflected on the officers concerned, who had worked well and whose conduct throughout the course had been so satisfactory, and, secondly, the credit that was due to his old friends, Fleet Surgeon G. Kirker and Fleet Surgeon P. W. Bassett Smith, whose capacity and teaching ability were well known and very much appreciated. The Director-General had alluded to the great interest that he (the speaker) had taken in the medical department since he had been associated with it. To this he could say that among his various duties no other had been so interesting and that in his endeavours to deal with the many questions relating to the medical, hospital, and nursing service, he had been most willingly and ably helped by the Director-General and his department and that it was a good deal due to their steady work that the various proposals had been brought to a satisfactory conclusion. He said that the medical profession was second to none and that it afforded special opportunities of doing good which were attached to no other. Looking back to the time when he first went to sea—about 40 years ago—no reminiscence, he said, was more vivid than his recollection of the medical officers' work in his first ship on an occasion when, cut off from nurses, hospitals, and their professional brethren on shore, they successfully combated a serious outbreak of small-pox with a simple devotion to duty which all admired. He had also seen them with the same satisfaction on active service and alluded to the heroic conduct of Staff Surgeon W. J. Maillard who was awarded by his Sovereign the coveted distinction of the Victoria Cross and whose death recently they had to deplore. He was a fine young and distinguished officer with high professional attainments who showed a true devotion to duty. The surgeon in a ship held a unique position of friend and adviser and very much depended on him. There were many little things he could do in the matter of his duty in connexion with the health and comfort of the ship's company, and a captain who had a good adviser in the medical officer was materially helped in conducting the service efficiently. A number of changes and considerable improvements had taken place during the last few years and others were in hand. It was desirable that in accordance with the permission recently promulgated surgeons should qualify for staff surgeon after five years' service in order to obtain early advancement. After a vote of thanks to Admiral Durnford, proposed by Inspector-General R. W. Coppinger, the proceedings terminated by a luncheon.

Surgeon-Colonel J. Richardson, retired, I.M.S., has been appointed Honorary Physician to the King in place of Surgeon-General W. R. Rice, C.S.I., deceased.

Correspondence.

"Audi alteram partem.

A NOTE ON THE PRACTICE OF DIRECT OR "IMMEDIATE" AUSCULTATION.

To the Editors of THE LANCET

SIRS,—The practice of auscultation in the minds of not a few members of our profession is inseparably associated with the use of the stethoscope Direct or "immediate" auscultation by the application of the ear itself to the chest finds, indeed, respectful mention in text books but in practice it is generally either ignored or regarded as an imperfect substitute for stethoscopy Accident led me some 12 years ago to perceive that the direct method possesses some special advantages of its own , further observation confirmed that belief and for the last ten years I have employed this method systematically and almost exclusively in the examination of the bases and back of the chest, using the stethoscope in those regions save in infants, for supplementary purposes only So familiar, indeed, had this practice become to me that I only lately realised how little it was in general use or the advantages of it were recognised A note upon the subject may, therefore, not be altogether useless

The conditions of auscultation at the back of the chest, particularly at the bases, differ materially from those in the front and at the sides The greater thickness of chest wall that sounds originating in the lung and pleura have to traverse before reaching the surface of the back necessarily tends to greater dispersion and greater loss of audibility than is the case elsewhere The lesions affecting the bases are, moreover for the most part lesions of wider extension than those for which the apices have to be searched In auscultation of the back and bases, therefore, exact localisation of signs is, generally speaking, matter of less concern than certainty of detection The flexible external ear, which admits of being exactly applied to any part of the back can be used to collect vibrations from a much wider area than is covered by the rigid chest-piece of the stethoscope, the practicable size of which is limited by the curves of the thoracic surface while the avoidance of the interposing conductor at the same time reduces the loss of sound in transmission As the area to be explored can be covered by the ear with fewer shiftings of its position than the stethoscope requires, the method has the further incidental advantage of saving the physician's time and sparing fatigue to his patient.

Of the application of the method there is little to be said that is not obvious The patient sitting up in bed or standing or sitting with the shoulders bent forwards, a napkin or fine towel may be placed over the back of the head and chest and held in position with one hand while the ear of the same side is passed rapidly over the regions to be examined The tactile sensibility of the ear is generally sufficient for purposes of localisation, but it may be supplemented, if necessary, by the fingers of the disengaged hand By directing the patient to lift his arm over his head and moving the napkin to cover the axilla direct examination may be extended to the side of the chest Even if the patient is too ill to sit up it can be conducted without much difficulty if he is made to lie first on one side and then on the other

The accident which drew my attention to the method was the discovery that in a stout patient the subject of pneumothorax amphoric breathing could be plainly heard over a wide area by the unassisted ear though it was hardly discernible by the stethoscope I have not again repeated this observation in so marked a form, but a few years' practice of the method was sufficient to convince me that the greater number of auscultatory signs at the back, both respiratory and vocal, are more easily detected, better defined, and more clearly to be discriminated from each other by this method than when the stethoscope alone is used More particularly I have found this the case —1 In cases of acute pneumonia when inflammatory consolidation commencing in the deeper parts of the lung is approaching the surface 2 In other cases of deep seated consolidation 3 In the detection of cavernous signs, particularly in the case of cavities of bronchiectatic origin situated in the bases 4 In the detection of asthmatic sibilus 5 In the detection and discrimination of moist sounds at the bases, especially those due to œdema of the lungs I have repeatedly found the fine crepitations indicative of the onset of œdema audible over a considerable area by the ear directly applied when nothing was discernible by the stethoscope At all stages of œdema I find the character of the rales and crepitations due to it more precisely defined by direct auscultation, so that it is possible more certainly to separate them from the râles and crepitations of bronchitic or pneumonic origin by which they may be accompanied 6 Most markedly in the diagnosis of pleural effusions and the determination of indications for paracentesis In some of the most recent works on diseases of the chest I find it stated that over the seat of considerable accumulations of fluid in the pleural cavity, besides dulness, immobility, and absence of vocal fremitus, we should expect to find a diminution or total absence of the breath and voice sounds In children, it is added, tubular breathing and bronchophony may be heard, but only exceptionally in adults If so uniform an account may be taken to represent the general experience of clinicians I am forced to infer that the more customary methods of examination fail to reveal all that may be detected by direct auscultation Over the area of any considerable accumulation of fluid in the adult chest, be its origin inflammatory or dropsical, the unassisted ear, according to my own experience seldom or never fails to discern a more or less distant but quite distinct tubular breathing and bronchophony, commencing at or about its upper margin and extending to the base

The tubular sounds thus heard, except in some extreme accumulations, have a special quality of their own which is characteristic, which after a little practice it is not easy to mistake, and which enables them to be distinguished without much difficulty from the similar sounds produced by pneumonic consolidation The difference is not merely one of "distance" or faintness , it is as markedly one of pitch The pitch of both sounds is always high, much higher than is usual in inflammatory consolidation of the base, though a similar pitch is not rarely found in apical pneumonia The breath sound is always "dry," never broken by crepitations The bronchophonic sound is not to be confounded with ægophony I have for many years regarded and pointed out these sounds as the most trustworthy signs we possess of an accumulation of fluid and the most definite indication for paracentesis should the circumstances of the case otherwise suggest it.

As a practical diagnostic criterion I have found them of no small value The diagnosis of a fluid accumulation, when it has reached such a degree as to distend the side of the chest, to deflect the mediastinum, to raise the ribs, and to cause the intercostal spaces to bulge, is usually a simple matter, but in the treatment of pleurisy we cannot afford to wait till these extreme results develop and paracentesis may become desirable while the quantity of fluid is still far short of that necessary to produce them 30 ounces of fluid or even more may be present in the chest and recoverable by tapping without any of these obvious signs of its presence being available and the distinction between an accumulation of fluid and a fibrinous pleurisy, apart from the signs I have described, is in such cases not free from difficulty So great, indeed, is the difficulty that many experienced clinicians profess to regard an exploratory puncture as the only certain means of decision unless the aid of radiography happens to be available A loose fibrinous layer of moderate thickness may cut off not only the vocal fremitus but the respiratory and voice sounds as effectually as a layer of fluid Measurement of the chest cannot be relied on , few chests are quite symmetrical and the side containing a fluid effusion may show no greater, or even a lesser girth than the sound side Minor degrees of displacement of the heart cannot, for many reasons, be always certainly determined Neither the rate of respiration nor the patient's symptoms give trustworthy guidance The rate may be rapid and the breathlessness severe in a purely fibrinous case On the other hand, I have removed 40 ounces of fluid from the chest of a patient whose respiration rate was only 24 and over 30 ounces from one who complained of no trouble of breathing at all The area of vertical extension of a pleurisy may, moreover, be seriously deceptive, especially when fluid has accumulated between the lung and the diaphragm On one occasion I took 37 ounces of serous fluid from a patient in whom the signs of effusion extended no higher than the ninth dorsal spinous process behind and the seventh rib in the mid axillary line In such a case one would have expected to find the action of the diaphragm seriously interfered with, but a fair amount of abdominal respiration was actually present. I was guided to the operation solely by the presence of the distant tubular breathing and bronchophony of the quality I have attempted to describe.

It would be vain to claim an absolutely invariable significance for any group of physical signs found in the chest, but as far as my observations go these signs possess as constant a significance as can be predicated of any that we know. I have never failed to find abundant fluid in performing paracentesis where they were present; I can scarcely recall an instance in which an exploratory paracentesis yielded more than a few ounces of fluid unless they were to be heard. If these facts alone should be found to be of general application I shall, I think, need no further excuse for having invited a more systematic attention to the practice of direct auscultation than it obtains at present.

I am, Sirs, yours faithfully,
ISAMBARD OWEN, M.D. Cantab., F.R.C.P. Lond.
Sept. 29th, 1903.

THE TRANSMISSION OF YELLOW FEVER.

To the Editors of THE LANCET.

SIRS,—In THE LANCET of August 1st, p. 345, in the letter of your special correspondent in New York, mention is made of me as one of the physicians who are not entirely in accord with the conclusion of the United States Army Yellow Fever Board of 1900 that "the female mosquito of the species stegomyia fasciata is the only and exclusive conveyor of yellow fever from one person to another." What I consider scientifically vulnerable points in the series of experiments carried on by the Yellow Fever Commission of 1900 in the island of Cuba are the following, some of which your correspondent has quoted. The house in which the experiments were made was an artificial house, under completely abnormal conditions never to be found in a living Cuban house. It was more in the nature of an autoclave than a dwelling-place. This house was not located in the city of Havana, as it should have been, but outside in the country, nine kilometres away to the south west, and at about four kilometres from the sea coast, where the recognised dangerous sea air could not reach it. There was not due care in the selection of the non-immune persons with whom the infection experiments were made, probably some already immunes to yellow fever being among them. These individuals experimented with did not remain all day in that house but only went in there to sleep after dark and early in the morning came out of the house and with changed clothes remained all the rest of the day in the open air in tents placed at a distance. I call this unsteadiness, this ebbing and flowing of the experiments, a sort of Penelope's work. Besides, it is a well-known physiological law that during sleep the human organism is at its minimum of energy and activity, the nearest to death. The time selected to try the infection experiments, therefore, was precisely when the organism of those experimented with was the least liable to contract the disease. In spite of all those favourable circumstances the statistics presented (44·4 per cent.) are not, in my opinion, sufficiently convincing.

A few facts which demonstrate that hygiene, sanitary reforms, isolation of the sick patients, the absence of the large number of poorly nourished, poorly clad, and generally neglected Spanish soldiers, and the immigration department and observation hospital in connexion with it established by the United States Government have been more powerful factors in the eradication of yellow fever from the island of Cuba than the mere protection of sick patients from the bites of mosquitoes, are the following. In the city of Havana alone mosquitoes have been killed and crude petroleum has been used in their breeding places to extirpate yellow fever. In no other city or town of the island has this measure been put into practice and yet yellow fever has disappeared not only from Havana but equally as well from Santiago, Matanzas, Cienfuegos, Cárdenas, Sagua, Manzanillo, Gibara, and all the other cities and towns of the island, no matter how great the distance from Havana With the American occupation of Cuba from 140,000 to 160,000 Spanish soldiers went immediately out of it and were sent back to their native country. The large number of the Spanish Government civil employés who every month used to go to Cuba, all of them non-immunes to yellow fever, do not go now any more to that island. This immense amount of human flesh, which constituted before the fuel that kept burning the funeral pile of yellow fever victims, has completely been put out of the island. In consequence of the cleanliness, the sanitary reforms, the considerably better hygiene public and private, and the prophylactic measures instituted by the United States Government in Cuba and continued by the present Cuban Government, not only yellow fever, but also small-pox, both of which diseases were there formerly epidemic, have been eradicated and the general death-rate in each and every city all over the island has considerably decreased. The newly established immigration department and its stringent laws have also greatly contributed to the eradication of yellow fever in Cuba.

I am, Sirs, yours faithfully,
A. M. FERNANDEZ DE YBARRA, B A., M.D.,
Medical Biographer of Christopher Columbus.
New York, August 15th, 1903.

THE MEDICAL REGISTER.

To the Editors of THE LANCET.

SIRS,—In the interests of the profession may I ask you to be good enough to draw attention in your next issue to the importance to practitioners of keeping their addresses correct in the Medical Register. The chief points to which attention should be called are:—

1. The Register should not be confused with the Medical Directory as is so often done. Changes should be notified to this office by practitioners themselves and they should be careful to notice that a postcard is received in acknowledgment.

2. The present system is to send a circular of inquiry to one-third of the practitioners on the Register residing in the United Kingdom, *from whom no communication has been* received during the past 12 months, in each successive year during the period when there is no election of Direct Representatives. This year circulars were sent to practitioners from A to G inclusive and any person within those letters who has not received a circular should communicate with this office at once.

3. Anyone who is doubtful if his address is correct should inquire at the office without delay.

In past years you have kindly done your best to assist me in my efforts to save practitioners from the grave inconvenience of finding that their names do not appear on the Register because their whereabouts cannot be ascertained and I hope, therefore, that you will continue to give us the benefit of your valuable assistance in the matter.

I am, Sirs, yours faithfully,
H. E. ALLEN, Registrar.
229, Oxford-street, London, W., Oct. 2nd, 1903.

THE PREVENTION OF HORSE-DUNG IN THE STREETS.

To the Editors of THE LANCET.

SIRS,—With all the hygienic improvements hitherto effected no attention seems to have been paid to the prevention of the streets of towns from being contaminated by the dung of carriage horses. It is true that a great deal of money is expended in sweeping up the dung but it is never effectual, for part of the fluid and semi-fluid constituents adhere to the ground and by decomposing, especially in warm weather, diffuse an offensive smell through the whole atmosphere which people have to breathe, whether in the streets or in their own houses. Add to this the nuisance of clouds of dust, consisting to a great extent of fine particles of dried dung-laden with an abundance of microbes of various kinds, blown about and taken into the mouth and lungs at every breath or eaten up with the provisions exposed for sale in the shops.

All this cannot be without injurious effects upon the health of the inhabitants of a town and it might even be the means of disseminating certain diseases in man as well as in animals. It is no less objectionable from an æsthetic point of view. It being therefore undeniable that the existing state of things is a great nuisance and is put up with simply because no effectual remedy had hitherto been proposed, I have tried for some time to solve this sanitary problem in a radical manner and think I have succeeded.

I have constructed a simple apparatus which I call "an automatic dung trap" for carriage horses which entirely prevents any of the droppings and even the urine from falling on the roads. I inclose a photograph of a horse and carriage to illustrate the apparatus as applied for actual use. On slightly magnifying the parts become very clear. It consists of a suitable receiver or dung trap fixed to some convenient part of the vehicle, as the axle of the front wheels for example, and of a shoot or collector of some flexible waterproof material, attached at one end to the breech strap or its equivalent and at the other end to an outlet tube extending from the top of the receiver in the direction of the animal's breech. The receiver or dung trap contains an open-topped drawer or removable lining, which can be withdrawn and replaced by its handle at the back of the receiver. The shoot or collector has an expanded trough-like shape near the breech just large enough to catch the dung, but narrows down to the diameter of the inlet tube. The inlet tube is pivoted to the top of the receiver in such a manner that the shoot will always adjust itself to extend in a straight line from the breech strap, notwithstanding the variations in the heights of different horses.

Whether the animal is standing or running, its dung (and its urine in the case of a mare) is caught by the shoot or collector and travels by gravity along the same into the removable drawer, which can be removed, emptied, and cleaned periodically. With regard to the urine of a male animal, if desired, a funnel-shaped receptacle may be arranged in the proper position to catch the urine and convey it by means of a rubber tube into the dung trap or separate receptacle. There is also a valvular arrangement at the inlet tube of the receiver to allow the dung and urine to pass freely into the receiver, but to prevent any smell coming out. The shoot and receiver are permanently fastened together and to the carriage. When a horse is put to the carriage, all that is required is to attach the shoot by means of clamps or straps and buckles, which can be done in a couple of minutes. It will be seen that, with the exception of the receiver which is placed quite out of the way, everything is soft and flexible, and as no part of it touches the horse there is nothing in the least to frighten the most timid animal.

The only possible objection that I can see is its unusual or novel appearance. A glance at the photograph will show that it is not very obtrusive or ugly, and I think, considering its great utility, people will soon get used to its appearance as they have to the splashboard or any other necessary part of a carriage. I am convinced that if this apparatus were universally adopted the streets of towns would become almost as clean and as wholesome as a garden walk, disease and mortality would diminish, and the comforts of town life would considerably increase. I do not enter into the economical question for that will at once suggest itself to municipal authorities, the enormous expense of scavenging the streets being necessitated mainly by horse dung.

I am, Sirs, yours faithfully,
J. A. CALANTARIENTS, M.D. Edin.
Scarborough, Sept. 29th, 1903.

⁂ The apparatus as shown in the photograph is not at all obtrusively noticeable.—ED. L.

WHAT IS SCIATICA?

To the Editors of THE LANCET.

SIRS,—Dr. W. Bruce, in his letter in THE LANCET of Sept. 12th, p. 785, shows that he has not quite grasped either the substance or the spirit of my letter of August 29th, p. 633. I, like many other general practitioners, scan weekly the columns of THE LANCET to keep myself acquainted early with any new light thrown on disease or injury, and a paper like Dr. Bruce's professing to revolutionise our conception of sciatica is well calculated to attract the attention of the general practitioner. Sciatica is a common and frequently an intractable complaint, and if Dr. Bruce has given us a clue to its more effectual treatment he is worthy of our gratitude.

Having read Dr. Bruce's paper I was prompted to give details of a case on which his theory had direct bearing. A man with double arthritis deformans affecting the hip-joints is a martyr to sciatica; he sustains an intracapsular fracture of the left femoral neck, union is not good, but the sciatica on that side is cured. Three years later he gets an intracapsular fracture of the right femoral neck and comes into my hands. He is treated with extension; union is fair and the sciatica is cured this side also. I ask if the sciatica was cured by the long rest or the long stretching of the sciatic nerve? I cannot believe that an intercapsular fracture with a few weeks' rest will cure old-standing arthritis deformans of a joint and if it will not, surely the cure must be attributed to the stretching. I believe it is an accepted pathological doctrine that the group of toxins which produce an arthritis deformans may also produce a neuritis and the facts of the case seem to me to warrant the opinion that while the sciatica was no doubt in the first place excited by the joint disease there was an actual neuritis of the sciatic nerves which was benefited, as other cases of sciatica have been benefited, by stretching.

Dr. Bruce in his letter confesses that he may have put his case too strongly and thereby relieves me of the onus of suggesting that he has fallen into the common temptation of the man who has a new truth to tell, the temptation of overstating his case for the sake of emphasis. I may be wrong, but it seems to me also that he has not kept quite clear of partisanship in the strife between consulting physician and surgeon which prompts the one to declare that surgeons are prepared to use the knife for every complaint under the sun and the other to refer to the post-mortem room as the "physician's operating theatre." Therefore, to return to Dr. Bruce's use of the term "barbarous" as applied to an operation, I can only repeat that unless he has an alternative to offer he has no right himself to apply the term but should leave it to futurity. Dr. Bruce assumes, without any ground for the assumption beyond my not mentioning the fact specifically, that the first fracture in my case was not treated by extension. I did not think it necessary to mention its treatment, but as a matter of fact it was not treated by a prescription but by extension, as is customary, the bad result being ascribed to the man's constant restlessness from the sciatica in his other leg.

In concluding let me once more assure Dr. Bruce that his paper has provided me with most interesting and suggestive reading which I have no doubt will be of great use to me practically. I am not presuming to pit my knowledge and experience against his but have written purely from the point of view of the general practitioner, to which class of the profession his paper mostly appeals. Few of us care to under- [illegible] ic nerves or, *a* [illegible] it the responsi- [illegible] the physician [illegible] ored a success for the physicians.

I am, Sirs, yours faithfully,
Hampstead, Sept. 21st, 1903. J. S. MACKINTOSH.

THE PROBABLE ACTION OF CANCER PARASITES ON THE HUMAN BODY.

To the Editors of THE LANCET.

SIRS,—Virchow's artificial histological classification of tumours into homologous and heterologous growths has obscured the intellects of medical men with regard to cancerous and *other malignant disease for a considerable* time. But of late years there has been a tearing away from dogma and there is at present a strongly growing belief that malignant growths are caused by protozoal parasites. I believe that most of the evidence we at present possess, without conclusively proving this to be the case, strongly points that way. Allowing for the moment that cancer is a parasitic disease how can its peculiarities be explained? The most valuable theories are those which connect all the known [illegible] will not fit in with [illegible] in the following [illegible] eases fit. The [illegible] lial cells. Under [illegible] these cells, live with them symbiotically, dominate them, and stimulate them to increase and to multiply abnormally and thus is formed the primary tumour. Under the malign influence of the parasites the epithelial cells turn arrant traitors to their commonwealth and, like all renegades, become the bitterest foes of that to which they owe allegiance. After a time the dual semi-alien settlement sends forth colonies through the lymph streams which form other settlements wherever they can succeed in getting a foothold—secondary growths. The renegade epithelial cells and their guests prey on the tissues of the body and poison the sources of life by their combined excreta and lead to the destruction of the commonwealth—the human organism. The stroma of *cancer is the results of the efforts* made by the connective-tissue cells to combat the invaders after the latter have gained a lodgment. The species of parasites which cause sarcoma attack only the connective-tissue cells which become the renegades. Their colonies are despatched through the blood stream.

Is it possible to cultivate the parasites outside the human body? The answer to this question is: Probably the only possibility of cultivating a cancer or sarcoma outside the living body would be by placing an aseptic living section of a tumour in a constantly changing nutritive medium containing oxyhæmoglobin maintained at the body temperature. The difficulty of this undertaking, if not insuperable, would be extremely great. Where the parasites exist outside the human body is hard to surmise, but judging by analogy some insects, possibly flies or water animalcula, have something to do with their transmission.

It may seem premature to theorise about the parasites of malignant disease before they are definitely proved to exist but it is probable that their existence will never be mathematically proved according to Koch's data, yet most of us are morally certain that they are there. Action, it is said, must be based on theory. Sir Thomas Watson, long before the bacteriological age, held that tetanus was caused by the gradual manufacture of a strychnine like poison within the body. Sir Patrick Manson, long before it was proved by Ross, was convinced that the malarial parasites were carried by mosquitoes. A year before the malarial flagellated bodies were proved to be spermatozoa I suggested that they were such from their peculiar movements.

I am, Sirs, yours faithfully,
J. H WHELAN, M.D. R.U.I.,
Oct. 1st, 1903. Fleet Surgeon, R.N.

THE CARDIAC REFLEX OF ABRAMS.

To the Editors of THE LANCET.

SIRS,—Anent a recent annotation in THE LANCET[1] on the Cardiac Reflex of Abrams, one is constrained to conclude that the reflex in question can be elicited without the aid of the Roentgen rays. The latter observation, however, is only partially true, for the very evident reason that the cutaneous irritation necessary to produce the heart reflex will contemporaneously induce the lung reflex of dilatation which of itself will reduce the area of superficial cardiac dulness. The lung reflex being of shorter duration than the cardiac reflex, persistent reduction in the area of superficial cardiac dulness after a space of two minutes (a time exceeding that necessary for the lung borders to recede) would indicate that the diminished cardiac dulness was due to reduction in the heart volume and not to lung dilatation. In soliciting the aid of the cardiac reflex in diagnosis, prognosis, and treatment I almost invariably place sole reliance on the Roentgen rays with the fluorescent screen approximating the anterior chest wall. Unless one is specially skilled in mapping out the deep or relative cardiac dulness the Roentgen rays and not percussion should be our guide. You mention in your annotation that Merklen and Heitz of Paris have extended my observations and I beg to direct your attention to further facts concerning this reflex which I have elaborated since the publication of my original contributions on the subject. I have studied the reflex as an index to the condition of the myocardium and find in brief that when the cardiac muscle is beyond restitution in myocarditis and valvular diseases the cardiac reflex cannot be elicited. Heretofore this reflex was only observed in the transverse cardiac diameter, but it may also be noted in the sagittal diameter. The recognition of the heart reflex will often aid us in excluding the murmurs of a relative insufficiency. Here vigorous rubbing of the præcordium will temporarily dispel the latter murmurs. The principle involved in the latter manœuvre is essentially this: in relative insufficiency of the valves they have undergone no anatomic change but are no longer able to close the enlarged orifices of the heart, therefore vigorous friction of the præcordium by inducing the heart reflex will contract the myocardium and the orifices and will allow closure of the latter by the valves, at least temporarily. One may elicit the heart reflex by irritation of more remote regions. Thus one may easily observe by aid of the rays that when ammonia is inhaled there is decided recession of the cardiac ventricles (heart reflex), especially the left, and that this reflex may be more pronounced than when discharged through the skin of the præcordium. Ether and chloroform produce a similar though less pronounced effect. With the nose closed a similar though less pronounced effect of the vapours may be obtained, presumably by their action on the pharyngeal and laryngeal mucosa. In a few instances the vapours produced a veritable heart inhibition. I could observe no diminution in the intensity of the heart tones during the inhalation of the vapours, although sphygmograms showed a decided difference in the output of blood into the general circulation before and after the inhalation of ammonia. These observations suggest the wise expedient of cocainising the nasal mucosa before using an anæsthetic and further suggest the cogent necessity of anæsthetising the pharyngeal and laryngeal mucosa.

I am, Sirs, yours faithfully,
San Francisco, Sept. 18th, 1903. ALBERT ABRAMS.

TAKA-DIASTASE IN GOUTY DYSPEPSIA.

To the Editors of THE LANCET.

SIRS,—Every practitioner has under his care at various times very troublesome cases of dyspepsia associated with the gouty diathesis and the difficulty of keeping patients to a suitable dietary is well known. The stomach seems to digest well up to a certain point and appears to assimilate proteid matter far more readily than fats and carbohydrates; in fact, it is the faulty digestion of the latter, together with the sustained irritation caused by the decomposition of their by-products, that prevents the organ returning to a healthy tone. On the other hand, it is unquestionable that a diet almost exclusively composed of milk and farinaceous products is the one most suitable to produce permanent amelioration of the effects of uric acid saturation, and it is essential to put the stomach in a condition fit to receive and to use such foods. I have used salicylate of bismuth before meals for this purpose with good results as to relief of symptoms so long as its use was continued, but its curative action is practically *nil* and the mucous membrane reverts to the same irritable and atonic state when the drug is discontinued. Some samples of taka-diastase (Parke, Davis and Co.) were sent to me with notes on its value as a diastatic ferment with powerful action on starch. I tried it in two and a half grain tablets with a patient who had long suffered from this form of dyspepsia, with very gratifying results, and have since ordered it to be taken regularly after meals in this class of case until a satisfactory condition has been re-established. I should be glad to hear if my opinion on the value of this preparation is borne out by other practitioners and can heartily recommend a trial from my own experience of it.

I am, Sirs, yours faithfully,
L. WHEELER, M.B., B.Ch., B.A.O. R.U.I.
London, Sept. 30th, 1903.

FEVER AND CONVULSIONS DUE TO ASCARIDES.

To the Editors of THE LANCET.

SIRS,—Round worms in children of the poorer class are very common in the district round St. Day, near Redruth, and I have seen several cases of fever and convulsions, a few cases of incontinence of urine, and one case of chorea which could be traced to this condition. The children frequently vomit the worms and they are passed per rectum often in clusters. I used to put the cause down to the celebrated Cornish pasty which is the main food of the lower class. The outer covering of the pasty is often very lightly baked, while the contents are of various materials from underdone meat to cabbages and rotten potatoes. I imagine most medical men in practice in Cornwall have seen many peculiar symptoms which they have credited to the ascaris lumbricoides and it would be interesting and instructive to hear what, in their opinion, is the cause of this endemic disorder in the extreme south-west of England.

I am, Sirs, yours faithfully,
Streatham, S.W., Oct. 4th, 1903. E. H. WORTH.

To the Editors of THE LANCET.

SIRS,—Surely "worm fever" is not a complaint of extreme rarity, even though, as you note in THE LANCET of Sept. 26th (p. 898), "it is not recognised by British writers." Two cases, both of much interest at the time, have occurred in my short experience. Of these, one was that of a child six or seven years of age whom I admitted to the wards of a children's hospital as a case, probably, of typhoid fever, a diagnosis which was contradicted on the next morning by the finding of a large round worm in the cot, together with a remission of the symptoms. The other was that of a boy, aged 16 years, whom I admitted into the Great Northern Hospital in a comatose condition from which he could be with difficulty roused. The reflexes were markedly increased, Babinski's sign was present, and the temperature was raised. So ill did he seem that his friends were summoned on the following day. A few hours after they had settled themselves mournfully at the bedside both of them, uttering shrieks, fled down the ward. A nurse who investigated the cause of this alarm found a round worm struggling out of one of the nostrils of the patient who from that hour had no further symptoms. Were the latter produced by toxins, as suggested by Dr. Wettendorff, such rapid recovery would hardly have been expected.

---

A CASE OF LEPROSY.

To the Editors of THE LANCET.

SIRS,—With reference to the case of leprosy recorded in THE LANCET of Feb. 19th, 1898, p. 501, it may interest some of your readers to know that the patient died about nine months ago, apparently as a result of pulmonary complication of a few days' duration. This I learnt on making a recent inquiry, as the case came under my notice as well as that of others.

I am, Sirs, yours faithfully,
GEORGE PERNET.
Upper Gloucester-place, N.W., Oct. 2nd, 1903.

MEDICAL DOCTRINES OF HEREDITY.

To the Editors of THE LANCET.

SIRS,—Dr. J. Wiglesworth says that parental intemperance occurred in one sixth of his cases of insanity. I do not doubt him, but I think he will find it is quite as frequently an antecedent of sanity—among the inmates of a workhouse for instance. He adds that neither side in this discussion is capable of supplying definite proof of its contention. He is always so courteous, so obviously inspired by a right scientific desire to get at the truth, whatever it may be, that I am sure he is unconscious that he is a little unfair. The onus of proof rests with the side that makes a positive assertion. All that can reasonably be expected of their opponents is that they shall shatter any evidence brought forward. They cannot prove a negative. If I, for instance, declared that a dragon resided in the moon Dr. Wiglesworth would find it very difficult to disprove. Not an iota of evidence has been tendered for us to deal with though medical works are full of statements that parental disease and alcoholism affect offspring, though at the Swansea meeting speaker after speaker declared that he had seen any number of cases of it, and though I appealed to some of these gentlemen by name. Dr. Wiglesworth mentions Professor Cossar Ewart's pigeons. May I call his attention again to [illegible] were [illegible] cells which left the diseased male body and took up their abode in the healthy female body are supposed by Professor Ewart to have been incapable of recovery. Our experience of syphilis, for example, is similar. People recovered from that disease produce apparently healthy children. Nay, even while they are suffering they produce healthy offspring, provided the developing embryo is not affected with the actual virus. As an accurate scientific observer Professor Ewart is above suspicion, but his observations on this point were too few in number to constitute proof, especially in the face of a vast amount of contradictory evidence. Dr. Wiglesworth will remember Brown-Séquard's experiments on guinea-pigs. Brown-Séquard announced that by injuring parents he had produced defects in offspring. He thought that he was arguing for the transmission of acquirements As a fact he was maintaining the much more rational doctrine upheld by Dr. Wiglesworth. Not a single observer of the many who tried was able to repeat his results.

Dr. C. E. Scudamore thinks me too dogmatic. The quality of my dogmatism is by now apparent. In common with the majority of the scientific world I have refused to accept other people's dogmas when unsupported by any evidence and contradicted by a great deal of it. He says that I have "manipulated" his figures. If the readers of THE LANCET will turn to my last letter they will learn exactly what Dr. Scudamore means by manipulation. I must reserve the question as to whether "infectious diseases evolve and die out like higher species of animals, only with far greater rapidity," for future discussion.

The hair slopes in different parts of the human body in a number of different directions which are definite for the whole species. Dr. W. Kidd thinks that in each instance the slope is such as would naturally be produced by external influences and he wants us to believe it has become inborn in the race through the transmission of parental acquirements. In other words he wants us to believe that influences which have brushed the hair in one direction on the great toe, in another direction on the back, in a third direction on the head, in a fourth direction on the eyebrows, and so on, have each and all so separately affected the germ cells, situated far distant, that the traits which the parents acquired have become inborn in the descendants. And he wants us to believe this in spite of the facts (1) that no machinery for this amazing process has been discovered; (2) that the plant and animal kingdoms have been ransacked and no instance of the transmission of acquirements has yet been proved; and (3) that the tremendous and long-continued effects of use and disuse and of disease and hardship, as well as the amputation of dogs' tails and Jews' prepuces and the destruction of women's hymens have been without effect.

Dr. C. Mercier retires offended from this discussion. He declares that he has been misrepresented and he declines to deal with adversaries whose methods are so unscrupulous. Well, let us examine the two instances alleged by him. 1. In THE LANCET of August 22nd, p. 559, Dr. Mercier wrote: "By a parity of reasoning, if a long neck in a giraffe led to increased length of neck in the offspring every giraffe would now carry his head as high as the cross of St. Paul's. So easy is it to procure a *reductio ad absurdum* by ignoring essential conditions—in this case counteracting circumstances." In THE LANCET of August 29th, p 630, I wrote: "As to the necks of giraffes, certainly, if giraffes stretch their necks and the stretching is transmitted, I see no reason why their necks should not grow as high as the cross of St. Paul's. In fact, considering his beliefs—perhaps I should say his faith—I am lost in wonder that Dr. Mercier is not lost in wonder that they are not already higher." In THE LANCET of Sept. 5th, p. 731, he replied: "He asks me what the counteracting circumstances are which prevent a giraffe having a head as high as the cross of St. Paul's. There are many. One is that the weight of the neck would crush the animal." In THE LANCET of Sept. 12th, p. 785, Dr C. R Niven wrote: "With regard to the giraffe's neck and Dr. Mercier's 'parity of reasoning,'" if it be true, as Dr. Mercier holds it to be true, that acquired traits are transmissible and that the long neck of the giraffe is due to former giraffes stretching their necks, I agree with Dr. Reid in "seeing no reason," if Dr. Mercier demands it, "why their necks should not grow as high as the cross of St. Paul's." It is clear that Dr. Niven and I had both been led by Dr. Mercier's language to credit him with the belief that the giraffe's neck had grown long through the transmitted effects of stretching—a surprising belief which is an ordinary article of the creed of the school of thought which supposes that acquired characters are transmitted and to which Dr. Mercier belongs. Hitherto Dr. Mercier had done nothing to correct us; but the scent was growing hot and in THE LANCET of Sept. 19th, p. 844, he wrote: "In your next issue I expect to see that Dr. Niven credits me with the belief that ...... giraffes lengthen their necks by stretching." It must be admitted that Dr. Mercier's expectation was pre-eminently reasonable It was immediately gratified for in the same issue both Dr. Niven and I made the expected assumption *Hinc illæ lacrimæ.* 2 I raised a discussion by declaring that parental disease did not render offspring degenerate. Dr. Mercier vigorously attacked. Naturally I assumed that he did not agree and by way of beginning a passage wrote: "He asserts that alcohol, diseases, &c., affecting parents cause offspring to be degenerate ...... We have given reasons *for believing that the evidence is* unsatisfactory. In all humility what is the nature of the information he asks?" Dr. Mercier retorted: "If he will refer me to any such assertion of mine I shall be obliged to him. I deny I have made it." In astonishment I asked, "What then is his position in this discussion?" But Dr. Mercier is too deeply shocked to reply. He thinks that I ought to have apologised. Accordingly, he withdraws "from a discussion conducted by such methods" and indignantly asks, "What is to be thought of a cause that needs such expedients for its support?" The humour of the whole thing is that Dr. Mercier had persistently misinterpreted clear meanings and had declared that he had scalped Dr Niven and that Dr. H. Laing Gordon and Dr. A. Mearns Fraser had agreed with me only because we were all Scotsmen. It is unfortunate, moreover, that his exceedingly delicate sense of propriety awoke only at the precise moment when his scientific objections had been crushed, when he had been convicted of not knowing the elementary difference between an acquired and an inborn character without which all clear thinking on this subject is impossible, and when he had been invited to supply evidence of some remarkable discoveries in evolution which he said he had made.

I daresay it will be thought that I have pursued Dr. Mercier with unnecessary heat and cruelty. But, as he says, he has had previous experience of me, which implies that I have had some previous experience of him. I hope to appeal to the readers of THE LANCET on a future occasion and I am anxious to put an end, once and for all, to the petty evasions, personalities, impertinences, and irrelevancies which constitute his controversial stock-in-trade. I shall still be glad to deal with any scientific points he may raise, but I hope that any discussion that may occur in the future will be conducted rather in the spirit of Dr. Wiglesworth whom from the first I have recognised as a formidable opponent—formidable because, seeking truth only, instead of setting before me tasks which needed only a little paltry dialectic skill to overcome he was liable to confound me at any moment with facts beyond my knowledge and arguments beyond my power to refute. I am, Sirs, yours faithfully,

Southsea, Oct. 4th, 1903. G. ARCHDALL REID.

⁂ This correspondence must now be closed.—ED. L.

THE PATHOLOGY OF MISGOVERNMENT.

To the Editors of THE LANCET.

SIRS,—The sporadic atrocities of autocratic governments are occasionally explained away on the grounds of the temporarily diseased state of the absolute monarch reigning at the time. "Nature," quote the apologists, "being oppress'd, commands the mind to suffer with the body." King Asa was "diseased in his feet until his disease was exceeding great," and he it was who induced Ben-hadad to send "the captains of his armies against the cities of Israel; and they smote Ijon, and Dan, and Abel-maim, and all the store cities of Naphtali." But apparently Asa's disease was not contemporary with his moral delinquency and perhaps was an effect rather than a cause of it. On the other hand, a French writer[1] has recently advanced the hypothesis that the enormity known as the revocation of the Edict of Nantes, by Louis XIV., was the more or less direct result of disease and was brought about, not so much by evil counsels, as by an evil condition of the king's antrum. The king's physician, D'Aquin, relates that His Majesty suffered from very bad teeth which caused him constant pain. In 1685—the year of the revocation—dental caries was complicated by caries of the left maxillary sinus. All the teeth in the upper jaw on the left side were extracted and an enormous hole in the antrum resulted. This opening, although good for drainage, did not improve His Majesty's table manners, as every time he partook of a drink the fluid gushed from his nose "comme d'une véritable fontaine." Added to this, a marked fœtor developed, owing to the septic condition of the parts, which further increased the discomfort to himself and his environment. "Madame," said Louis one day to Madame de Maintenon, "je suis fatigué de supporter votre mauvaise humeur." "Sire," she retorted, "je supporte bien, moi, votre mauvaise odeur." Later in the year the actual cautery was extensively applied to the diseased area and the king made a tardy recovery. If we can divest ourselves of the belief that the revocation was the consummation of a definite policy we may think, What might the Protestants of France not have owed to a good dentist? I am, Sirs, yours faithfully,

Manchester, Oct. 5th, 1903. E. S. YONGE, M.D. Edin.

FOOD PRESERVATIVES.

To the Editors of THE LANCET.

SIRS,—My attention has been drawn to a paragraph in THE LANCET of Sept. 12th, p. 798, in which one of your New York correspondents draws attention to Dr. Wiley's experiments upon food preservatives and in which he says that two facts have been proved. This is not correct and I feel sure that Dr. Wiley would be the first to ask you to contradict this statement, as in his lecture before the National Association of Food Commissioners, which I have carefully read *in extenso*, he states repeatedly that although his experiments are practically completed he was unable then to make any announcement as to the conclusions which might be drawn from them. He further states that the large amount of data which had been accumulated would require several weeks of careful study before a report could be furnished by the department and therefore it seems very desirable that one should wait for the official report from the United States Bureau before Dr. Wiley is quoted as being either in favour of or against the use of preservatives. The paragraph in inverted commas is correctly reported except that he gives it, not as the summing up of the results of his work, but as the opinion which might be formed at the present time from the work of others, and your readers will have noticed that this opinion does not go further than expressing the desire that a declaration should in all cases accompany the use of preservatives.

The fact that he was about to visit England, France, and Germany to study the question shows that he still regards the problem as an open one, with the exception of the above proviso. I think it is exceedingly probable that he would have taken exception to the total prohibition motion which was brought forward and accepted at the recent meeting at the Congress of Hygiene and Demography at Brussels. I am, Sirs, yours faithfully,

SAMUEL RIDEAL.

OBSERVATIONS ON MASTICATION.

To the Editors of THE LANCET.

SIRS,—In reference to the remarks of Dr. Harry Campbell in THE LANCET, his theory, like many other theories, is good until compared with the results of practice. I personally have used a perfectly antiseptic and deodorant mouth wash at least once daily for over 20 years with the most beneficial results and have never noticed adverse reasons for discontinuing it. My digestive powers and my general health are decidedly better than they ever were at any time previous to the last five years. I think the prejudicial effects of diseased teeth and an unhealthy mouth upon the general health more than counterbalance the evil effects, real or imaginary, of the tooth brush and antiseptic mouth washes. The artificial life which the struggle for existence compels most of us to live must be taken into consideration and compared with the mode of living adopted by most savage races who, as a rule, have splendid teeth, but who go to bed and rise with the sun, live mostly in the open air, and use their teeth, as they should be used, for breaking down and masticating their food and to whom knives and forks are unknown or at least not used.

I have had the opportunity of examining the teeth of many natives in their more or less uncivilised state, from the Red Indians of North America, the négroes of Africa, to the more civilised Chinese, Japanese, and Indians of the East, and I have usually found them possessed of sound teeth, but so soon as they come under the influence of civilised life in Washington, Montreal, London, Paris, and other cities their teeth begin to degenerate, though their general health may remain good. As an instance amongst many that I could give, some years ago I had an opportunity of examining the teeth of three highly intelligent, well-educated West Coast negroes. When they arrived in this country for the purpose of study they had perfect sets of teeth in well-developed and well-shaped maxillæ; before these young men left this country on the completion of their studies I filled several teeth for them and prescribed an antiseptic mouth wash and tooth powders with beneficial results. Yet they had always used artificial means for cleaning their teeth. Many even of the most uncivilised natives employ artificial means for cleaning their teeth and yet are possessed of perfect dentures. I consider an antiseptic preparation for the teeth distinctly beneficial and in many cases a necessity.

THE MEDICAL DIRECTORY.

To the Editors of THE LANCET.

SIRS,—May we ask you to help us again in our desire to have the Medical Directory as up to date as possible by reminding your readers that all information for the 1904 issue should be sent to us without any further delay. It will not be safe for any member of the profession to rely on an alteration being possible after Oct. 24th.

We are, Sirs, yours faithfully,
J. & A. CHURCHILL.

NOTES FROM INDIA.

(FROM OUR SPECIAL CORRESPONDENT.)

The Mortality from Wild Animals and Snakes in India.—The Epidemic of Plague.—The Dangers of Indian Fairs.—The St. John Ambulance Association.

A RETURN recently issued by the Government gives the mortality from wild animals and snakes. Although not so numerous as in 1901 the deaths last year caused by wild animals totalled 2836 and those by snakes 23,166. Tigers caused 1046 deaths, more than half of which occurred in Bengal. In one district the increase of deaths from 31 to 63 is reported to have been due to the depredations of a man-eating tiger and in another district (Palama) an even larger number fell victims to a man-eater. Wolves caused 377 deaths, chiefly in the United Provinces. Snake-bites were, as usual, most numerous in Bengal—11,150 deaths in this province being recorded, 3258 of which occurred in the Patna division. In addition to this destruction of human life the number of cattle killed by wild animals was enormous—80,796 being reported for 1902 and 9019 more from snake-bites. In Bengal the destruction was greatest. The animals killed by tigers are returned at 30,555, by leopards at 38,211, by wolves 4719, and by hyenas 2387. To combat the annual destruction of life rewards are offered and 14,983 animals were killed for these rewards which amounted to over a lakh of rupees. The total number of snakes killed was 72,595. As the number of new licences issued free of cost under the Indian Arms Act for the destruction of wild animals was 9066, and as the total number in force amounted to 37,933, it can hardly be said that the holders were particularly active. Nearly three licences were in force for one wild animal killed.

There has been a pause in the hitherto rising mortality from plague, but 7748 deaths occurred throughout India last week from this cause. Of this total 4753 deaths were returned from the Bombay Presidency, 1330 from Central India, 473 from Hyderabad, 441 from Mysore, 350 from Berar, 117 from Madras Presidency, 107 from the Central Provinces, 88 from Bombay city, 38 from the Punjab, 18 from Calcutta, and 36 from Bengal. Plague has broken out again at Karachi and at Poona, it continues mildly at Ootacamund, it shows signs of increasing in Bombay city and Calcutta, and it has broken out in Broach. The published returns give no idea of the ravages of the disease at certain places During the past month, for example, plague has raged at the military station of Mhow with great severity. With a population of only 37,000 the deaths have risen to nearly 100 a day. At this rate the whole city would be destroyed in a little over a year. A popular rumour states that the British people had lost so many soldiers in the Boer war that they could not send out enough to control the large native population so they were trying to equalise numbers by the introduction of plague. Inoculation is, unfortunately, in abeyance and disinfection seems to be the only measure adopted. And what a broken reed. The course of the outbreak in Mhow is only one more proof of its uselessness. Epidemiologists have now the opportunity of watching the unimpeded course of plague in all the infected parts of India.

Indian fairs and pilgrimages which at different seasons attract so many thousands are a source of great danger in the spread of cholera, dysentery, and small-pox, but apparently not of plague. The great Hurdwar fair, for example, had 400,000 people assembled at one time and a daily average probably of 200,000, yet during the three weeks of its existence only 15 deaths from plague occurred and there was no evidence that the disease was subsequently disseminated. Cholera, on the other hand, broke out towards the close of the fair and the pilgrims in dispersing seem to have spread it over the Punjab and the United Provinces, thousands of deaths occurring within the few weeks ensuing. Were it not for the excellent sanitary arrangements made by the Government these fairs would probably be attended by a very high mortality. The greater facilities of travel by rail make these fairs larger and larger with each succeeding year.

The work of the St. John Ambulance Association in imparting instruction in first aid to the injured is being actively pushed, especially in the west of India. The railways fortunately are taking the matter up seriously and large numbers of classes have been held. The latest move is a competition open to Indian railway companies for the challenge shield and prizes offered by the association in the year 1904. Teams of five men, *bonâ-fide* servants of the railway company and holding first-aid certificates, will compete. I am sorry to hear that although a centre was formed in Calcutta there has been very little done for nearly two years.

Sept. 18th.

THE ELEVENTH INTERNATIONAL CONGRESS OF HYGIENE AND DEMOGRAPHY.

(FROM OUR SPECIAL SANITARY COMMISSIONER.)

THE FOURTH SECTION.

Debate on Ankylostomiasis.

UNDOUBTEDLY one feature of the Congress was the question of ankylostomiasis. It is but comparatively recently that general attention has been called to this disease, though it has spread to an alarming extent in Westphalia and other parts of Germany and in the Liège coalfields of Belgium. In Hungary, also, as many as 90 per cent. of the miners in certain districts suffered from this worm. It is present in some coal-mines of France and has made its appearance among the tin-mines of Cornwall. Consequently I need not apologise if I describe at length the debate held on this subject. It was the first question in the Section on Industrial Hygiene and in respect to factory legislation Belgium is undoubtedly much behind the times. Consequently some of the warmest discussions arose in this the Fourth Section. Conflicting interests came into play and it was no easy matter for the man of science to steer clear of party politics and financial influences. Some medical men were placed in the very awkward position of having to keep silent or of having to speak against the financial companies by whom they are employed and this in the presence of the directors of such companies. Six reporters had been appointed to deal with the question of ankylostomiasis and four lengthy printed reports were in the hands of the members of the congress before the section met. Dr. KUBORN, President of the Belgium Royal Society of Public Medicine, who occupied the chair, proposed that these reports should be taken as read and the discussion was at once opened by M. HARZÉ who is the "honorary director-general of the mines of Belgium." He explained that in 1899 the administration of mines desired to make regulations so as to check the spread of this disease but 12 out of 23 mining constituencies rejected such measures, qualifying them as "vexations and useless." The spectre of a general strike was even evoked. It seemed as if a word of command had gone round, for the opposition was simultaneous and similar in its arguments and phraseology. M. Harzé thought that much ignorance prevailed and that at universities there should be a chair on professional or trade diseases. He did not, however, believe that individuals could, by taking precautions, do much to check the malady. Several mining [illegible] gentlemen of [illegible] took every [illegible] but it was more important to examine under the microscope the dejecta of every miner. People still, and in spite of all that had been said, continued to spit in railway carriages or tramcars, so also the miner did not wait till he got home to relieve himself and when in the mine he would not give himself the trouble to go to the sanitary pail.

Dr. BREMONT agreed with M. Harzé and thought that though it was most necessary to teach the workmen, still the medical men must themselves first be taught and therefore he cordially approved of the creation of chairs on trade diseases.

M. HABETS, who is the manager or director of the Bonne-Espérance and the Bonne-Fortune coal mines, followed so as to describe what his company had done to combat the epidemic. Undoubtedly it was an advantage to hear what the mine owners themselves had to say; but, on the other hand, their presence might also have a deterrent effect on the freedom of discussion. In any case M. Habets explained that his engineers, acting under medical guidance, made the first analyses attempted in Belgium. They had a dispensary and employed a trained nurse to watch and to help in the analyses. As a result they found that about 60 per cent. of their miners were infested by the worm. Thereupon they drew up a set of rules which at first the miners showed some disposition to observe. Among other things, those who ate in the mine were not to touch their food with their fingers but to hold their bread with a piece of paper which was to be thrown away immediately. He could not find that any particular class of men were especially susceptible and some of the pit-brow workers, notably young women, had contracted the disease. Some cases had also been detected among phosphate workers and farm labourers. Last year the miners seemed to be tired of taking precautions and neglected them. So far M. Habets had trod on safe ground and the information which he gave to the section was welcome but when he continued by giving what he imagined were the reasons for the present negligence of the workmen he soon raised a storm. He said that when the workmen saw on the one hand that the infection did not produce very severe sickness and on the other hand that they would receive an indemnity which had been voted by the Liège County Council they had become careless. He thought workmen should be made to feel the evil consequences of their conduct. Dr. TERWAGNE (Antwerp) here exclaimed, "This would suppress public hygiene"; but M. Habets denied this, pointing out that here were mine-owners who had foreseen the danger and had done their best to cope with it.

Dr. BARBIER rose and insisted that the provincial government or county council of the province of Liège had been the first to act in the matter; he did not think that the amount of help given to the victims was enough to make them careless; they much preferred health, work, and the larger sum they could earn. As Dr. Barbier concluded it was evident that others were eager for the fray and wanted to attack or to defend M. Habets's aspersions on the miners but Dr. JORISSENNE intervened with a purely medical or therapeutic question. He claimed that the difficulty could be met if they had a treatment to efface the illness that was easy, cheap, and could be given even without the patients knowing that they were being treated. He then described a very bad case which had resisted all the usual methods of treatment. The man looked double his age, his brain was affected, he had albuminuria, and was on the point of death. Dr. Jorissenne thought of treating the patient with sulphur but sulphur alone would not kill the worms. It, however, produced some improvement. He found that the larvæ of flies could not resist terebene and therefore gave doses of terpene, sulphur, and as a stimulant to facilitate digestion some condurango. This treatment had restored his patient in spite of his desperate plight. In the case of many other sufferers from ankylostomiasis it had proved to be an infallible cure. As it was a perfectly inoffensive remedy and could do no injury to healthy persons he proposed that it should be given indiscriminately to every miner, whether in good or bad health, and thus the disease could be stamped out. After eight days of such treatment no more ova of the worm would be found in the dejecta.

M. CAVROT, who represents a constituency of miners in the Belgian Parliament and is vice-president of the Superior Council on Labour, followed with an energetic speech. As a simple workman he apologised for his audacity in addressing an audience of distinguished men of science. But if he was lacking in scientific education he had the practical education derived from actual work done in the mine and from personal suffering. The Superior Council on Labour was a State institution and in spite of the pressure brought to bear by the workmen who were admitted to that body, like other Government bodies it moved slowly. It had been said as an excuse that 12 out of 23 mining constituencies had objected to precautionary measures as "vexatious and useless" but this was the opinion of the mine-owners—the working miners were not represented. The miners, like other members of the community, required some educating, yet he would venture to affirm that in the central coalfields of Belgium not 5 per cent. of the pitmen would object to reasonable precautions. But first of all the necessity of cleanliness must be taught. Baths should be provided at every pit-brow. This had been done at Mariemont-Bascoup since 1883 and now the miners were proud of being clean. They would be ashamed to be seen in their soiled black clothes and nothing would induce them to leave the mine without first taking a bath and putting on respectable and clean clothes. It was absurd to imagine that the miners would expose themselves willingly to the risks of a serious disease. They set a higher value on health than the paltry 1*s.* 3*d.* per day given to some among them when it was proved that they had been seriously ill for more than a month. He concluded by hoping that the disinterested opinions of those present would awaken the Belgian Government and that at last something effective would be done to prevent the spread of this very terrible and wasting disease.

Dr. PERRONCITO of the University of Milan congratulated M. Cavrot on his declarations. Dr. Perroncito had studied ankylostomiasis in 1880 when it afflicted the workmen engaged in making the St. Gothard tunnel. Toxins were sometimes found in the urine but the worm was the main difficulty and evil. He agreed that cleanliness was the first necessity and the experience acquired in Hungary proved that by sanitary measures the disease could be overcome. For treatment he advocated the use of male fern.

Dr. HERMAN of Mons objected that it was impossible to disinfect a coal mine. The larvæ survived. No chemical method could be applied to a mine.

Dr. PERRONCITO replied that that was true only with regard to certain chemicals; mercury, for instance, was of no use. Carbolic acid was more effective.

M. GREGOIRE now rose to defend the action of the provincial government of Liège, he being a *député permanent* or member of the executive committee of that county council. He energetically protested against the idea that because his authority had helped the sufferers the workmen no longer took precautions. A benefit society had first denounced the evil as it found so many of its members on the sick list. Then it was that the Liège county council had appointed a medical commission to investigate, had organised a series of lectures, and had appealed to workmen's organisations to help. He found that the workmen readily accepted the advice of outsiders but looked upon the advice of their employers with suspicion. As for the subsidies, they found the disease so severe that many men had been unable to work for months and great distress prevailed; they only gave relief to the extent of one and a half francs per day after a man had been incapacitated for more than a month. It was a manifest exaggeration to say that men would seek sickness to secure such a pittance. He urged that the medical service organised by the employers was deficient in many respects. At Liège money had been voted to create a special and independent dispensary for the treatment of the disease.

Dr. DEJACE, who practised in the affected district, argued that expensive measures must not be taken too hastily. In any case, it was always useful to enforce cleanliness but they were not yet well informed as to the life-history of this worm, nor were they quite positive as to the nature of the disease which it produced. The symptoms were not always the same. At first they were very severe; now they were not so serious and nobody knew why there had been this diminution of intensity.

Here the first day's debate terminated but it was resumed with renewed ardour on the morrow and continued through the whole of the second day.

Dr. TÖTTS, of the Selmeczbanya coal-mines in Hungary, explained that in his district no less than 90 per cent. of the miners were afflicted by the disease. Very vigorous sanitary measures were enforced. Under the penalty of a fine the miners were compelled to use only the sanitary pails provided. The workmen themselves helped energetically to carry out the rules, denouncing those who were careless or indifferent. In time the disease completely disappeared.

Dr. TENHOLT, of the Bochum coalfields in Germany

Government medical adviser and chief medical officer of the
had had
thought
sis could
it it was
not propagated by water or by dust. In Westphalia every miner was examined before he was allowed to work in a coalpit. When numerous cases were reported from a coalfield the Government caused statistics to be drawn up and if it then appeared that the epidemic was serious a general examination of all the miners was ordered.

Here a French member of the Congress observed that many things were possible in Germany but not elsewhere. Germany with its system of compulsory insurance had all the necessary machinery and the financial means. The debate now became somewhat discursive and confused. It was asked whether the dejecta of every miner were to be examined before he was allowed to enter a mine. A case was mentioned of a miner who had presented the dejecta of his wife so as to avoid detection. To this it was answered that special closets must be made for the collection under efficient control of genuine specimens. Thereupon it was pointed out that such suggestions had already supplied the subject matter of many coarse caricatures and some ridicule.

M. WATTEYNE, mining engineer and delegate of the Belgian Ministry of Industry, said that there were three radical means of checking the epidemic: (1) so to improve the sanitation of mines as to render the development of ankylostomiasis impossible; (2) to prevent workmen who had contracted the disease from descending into the mines; and (3) to prevent the deposit of dejecta in the mines. For this it would be well to offer special privileges or rewards to the owners of the most sanitary mines. Great care must be taken that the sanitary installations provided for the miners were thoroughly clean and accessible. Special scavengers should be appointed for this purpose. But in all these matters sanction was required and therefore rules should be officially adopted such as already existed in Germany.

There then followed a great deal of discussion as to what should be the duties of colliery surgeons and as to the necessity of notifying all cases of ankylostomiasis. There was much division of opinion in regard to the person, the employer or the medical attendant, who should be responsible for such notification. Mr. ADOLPHE SMITH here rose observing that medical men had to earn their living and it was not fair to impose upon them duties which, if conscientiously performed, would be displeasing to those by whom they were employed and paid. Notification should be *rendered obligatory by law and paid for out of the public* purse, and any neglect to notify should be so punished that no one employing medical men could expect or request them to shirk this duty. In the performance of their public duties medical men should not be exposed to any pressure from those by whom they were employed, whether the employers were the mine owners or associations of workmen It was on this principle that the compulsory notification of certain diseases was enforced in England. Many of the Belgian colliery surgeons present were well pleased by this suggestion but did *not venture to press it* forward in the presence of the directors of the mining companies by whom they were employed. Indeed, what seems to be especially needed in Belgium is a staff of medical men holding an absolutely independent position.

M. CAVROT, speaking on behalf of the pitmen, brought forward a proposal demanding that baths and closets should be established close to the pits; that the mud that accumulated in the pits should be removed; that plenty of fresh air and pure water should be supplied; and that general *cleanliness should be rendered obligatory* on the part of employers and employed.

Dr. DELBASTAILLE (Liège) urged that baths, though beneficial, did not prevent ankylostomiasis.

At last the section agreed to adopt the following motion:—

> Miners can only be admitted into the mines after a complete medical examination held in view of ankylostomiasis.
>
> The notification to the competent authorities of all cases known to the chiefs of the mines is obligatory.
>
> It is necessary to establish suitable and comfortable water-closets at the *surface* and *recipients* at the bottom of the *mines*.

After carrying this motion the section adjourned at a late hour for lunch. It afterwards re-assembled and resumed the discussion with undiminished eagerness and interest. A great number of recommendations were made and the question of the dryness of the mines arose. As moisture favours the spread of the disease and dryness helps to produce explosions, which is the lesser of the two evils? In regard to baths it was shown that the disease had been known to prevail in mines where there were model douches established. Sometimes water from the mine was used for bathing purposes and the douche was then the means of spreading the disease instead of preventing it. So here as elsewhere a pure water-supply was one of the first requisites. M. CAVROT said that the mines of Belgium yielded from 40 to 60 million francs net profit per annum, yet there was a great reluctance to incur a small expense so that cleanliness might be enforced. To this it was replied that the mine owners had spent 10,000,000 francs to improve the ventilation of the mines and had thus not only reduced the frequency of explosions but checked the prevalence of anæmia among the miners. After further discussion and some recriminations the debate was at last brought to a close and this is the final motion adopted:—

> stomiasis.
>
> programme of pr
> spread of alcohol
> the evening clas
> mining compan
> personal hygiene
> lecture on ankylostoma duodenale.

BIRMINGHAM.

(*FROM OUR OWN CORRESPONDENT.*)

Boarding School for Feeble-minded Children.

UNDER the Elementary Education (Defective and Epileptic Children) Act, 1899, education authorities are empowered to build and to maintain boarding schools for mentally deficient children and to permit them to remain therein until the age of 16 years. A school of this kind has been provided for Lancashire and Cheshire children in which the cost of maintenance and education is found to be about £27 per head per annum, towards which the Government will contribute between £4 and £5 per head per annum. The late school board appointed a committee of its own number with several medical men to report upon the best method of dealing with this class of child. The committee reported in favour of the *provision* of a boarding school for the reception of some of the worst cases—those with exceptionally bad homes and those whose feeble-mindedness was of a moral character. In addition to this the committee also made the following recommendation:—

> That while recognising that the powers of the board cease when the children attain the age of 16, yet in view of the fact that most of
>
> colony.

This report having been received by the late school board a short time before its dissolution was never adopted or acted upon. It was again brought up at the last meeting of the education committee and a recommendation was laid before that body that inquiries should be made as to sites and plans prepared for the ere
children. This
and the prelimi
with. A perusal of the report of the subcommittee for special schools certainly *leads one to think that* in thus acting the education committee has taken a most desirable step, though it needs a subtle mind to distinguish between the cases which are to be sent to one of these schools until the age of 16 years and then let loose upon the public and

those other and to all appearances very similar children who are shut up in the imbecile wards of a public asylum till the end of their days.

Sanitary Conference in Birmingham.

A provincial meeting of the Sanitary Institute has recently been held in this city. The members visited the new crematorium which will be opened shortly and also the works of the Tame and Rea district drainage board, where they were conducted over the sewage farm. A lengthy discussion on methods of treating sewage took place at a meeting held in the medical theatre of the University over which Dr. Alfred Hill presided.

Vaccination Case: Personal Service of Summons.

A case of more than local interest was decided a few days ago in the Birmingham magistrates' court. Mr. Cave, for the prosecution, explained that in the first place a notice was given by the vaccination officer to the defendant to have his child vaccinated. This notice was disregarded; a summons was issued and an order was made that the child should be vaccinated within 14 days. That order was served by being left by a police constable at the defendant's house with a woman who was presumed to be the defendant's wife. The order was not obeyed and upon a subsequent occasion the present summons was issued. When it came before the court an adjournment was asked for in order that Mr. Schultess-Young should be instructed. Mr. Cave stated that the point to be decided was whether, as a matter of law, the service of the order, having been left with the wife in the man's house, was a good service. Mr. Schultess-Young pointed out that other cases had been tried in the Birmingham courts on this very point and dismissed. Mr. Carter, the magistrate's clerk, admitted that this was so. In these previous cases officers had stated that the summons was not served personally. He thought, in the circumstances, that the evidence was not sufficient and he advised the magistrates to dismiss the cases. The anti-vaccination people saw an opening and they had made the most of it ever since. He had, however, come to the conclusion that his opinion in regard to the previous cases was wrong. He took the view now from the Act that the order should be served upon the defendant, not necessarily personally. There was no provision with regard to the service of the order. It was not prescribed that there should be personal service—it was enough for the magistrates to know that the order had come to the knowledge of the defendant. In this case he believed that they were satisfied that it had come to the defendant's knowledge. Mr. Schultess-Young argued that Mr. Carter's first opinion was more correct than his second and pointed out that some London stipendiaries had taken the view that they could not go against the well-known principle of law that orders must be served personally upon defendants. A number of other legal arguments brought forward by counsel did not convince the magistrates who decided against the defendant and found that the order was properly served. Mr. Schultess-Young thought they were unique in their decision but the defendant was fined 10*s*. and costs (including 2*s*. 6*d*. for the vaccination officer) or 14 days' imprisonment in default.

"Beef Lard."

At Wednesbury police-court a short time ago a local shopkeeper was summoned for selling dripping containing 20 per cent. of cotton-seed oil. An inspector visited the shop and was shown a substance which he was told was supplied to the defendant as "beef lard" but which she sold as dripping. The defendant stated that she believed it to be dripping and the stipendiary in imposing a fine of £2 expressed his belief that she was acting unwittingly. After this case had been decided upon Andrew Clement and Sons, produce brokers, Greenwood-street, Manchester, were charged with selling beef lard which was not of the nature, substance, and quality demanded by the purchaser. The material supplied under this name to local shopkeepers was found to contain 50 per cent. of cotton-seed oil. The county analyst said he expected to find beef lard to consist of beef fat of the consistency of lard. He agreed that there was no standard fixed for beef lard but it seemed to him to be a name to deceive. The manager to a local firm said he had been purchasing beef lard from the defendants for two years and was under the impression that it was the waste or rough fat of the ox. He had asked the defendants whether it was beef dripping and had been told that it was not—that it was beef lard. For the defence a number of witnesses were called to show that beef lard was a well-known article of commerce and was understood to be composed in part of cotton-seed oil. One witness stated that he was formerly in Aberdeen with various American lard importers and that he sold beef lard as long as 14 or 15 years ago in Scotland. It was used for frying purposes and also for confectionery, these being the objects for which it was specially intended. Beef lard was not quoted upon any of the markets but customers knew perfectly well what its ingredients were. Lewis Maclellen, oil importer and refiner, Glasgow, said that an extensive trade was done in this substance in England, Scotland, and Ireland, the trade in England having been developed in quite recent years. It was used for purposes for which beef fat was too hard and the cotton-seed oil was used to reduce it to the consistence of lard. A member of a firm of biscuit manufacturers at Wigan said that he had used beef lard for 15 years, buying it in tons at a time. He should think that nearly all biscuit manufacturers used it. He quite understood that it contained cotton-seed oil; unless it did it would not answer its purposes. Other witnesses gave evidence that beef lard was in common use in the north of England and that the term was well understood. The stipendiary magistrate said the case arose because of the unfortunate name given to the compound. He would not say it was invented to deceive the public but there was no doubt that the name lent itself to deception. He, however, must find that it was a well-known article on the market and that no standard had been fixed for it. It was sold as beef lard and the purchaser received it as beef lard. In these circumstances he dismissed the case.

Opening of the Medical Session of the University.

The opening of the medical session of the University took place on Oct. 5th, when a conversazione was held in the medical buildings. The Dean, Professor B. C. A. Windle, F.R.S., received the visitors who numbered over 250. The principal feature of the evening was the address which was delivered by Sir Victor Horsley, F.R C.S. Eng., F.R.S., the Dean of the Faculty being in the chair. Sir Victor Horsley's address was a vigorous reply to Sir William Anson's speech at Manchester and an earnest demand for a larger measure of State aid for university institutions and for medical education. Under the present Government, he said, the Education Department had been placed in the hands of those whose ideas are regulated by the sterile training in dead languages and somewhat moribund system of philosophy, unfortunately characteristic of an old University like Oxford. Apparently it had not occurred to the Parliamentary Secretary of the Board of Education that to the ordinary person the obvious way of obtaining an intelligent population was to provide it with the highest and best means of educating itself and to increase those means in the midst of every populous district. Alluding to the chaotic condition of medical education and medical examinations and referring specially to the difficulties which have arisen between the General Medical Council and the Royal Colleges in England the lecturer earnestly advocated the establishment of a "one-portal" system. When this had been attained the universities would be free to pursue their proper policy of imparting the highest knowledge to their students and would be freed from the task of giving a mere qualification. He suggested that the degree of M.B should be abandoned since it was really only a kind of licence to practise, that universities should give no degree to any student who had not previously obtained a medical qualification to practise, and that the degree then given should be that of doctor of medicine. He admitted that at the present time want of funds made it almost impossible for any university to adopt such a policy, but that such a reason could be put forward was an eloquent testimony of the need for further and generous endowments of medical as well as other branches of university education. It was unjust to expect the parents or guardians of students to bear the heavy expenses of professional education. The alternative was State aid. He suggested that while the British Association was endeavouring to educate public opinion on the necessity of making university maintenance a prominent political question, the universities should coöperate and agree upon a definite programme of State aid. A vote of thanks to the lecturer proposed by Principal Sir Oliver Lodge and seconded by Professor H. G. Barling was warmly accorded.

MANCHESTER.

(FROM OUR OWN CORRESPONDENT.)

Royal Albert Asylum and Tuberculous Patients.

THE seventh quinquennial festival of the Royal Albert Asylum, Lancaster, was celebrated on Sept. 23rd. Sir J. T. Hibbert presided. He said that Lancaster, including Lord Ashton's donation of £15,000 for the new wing, had contributed no less than £36,321 and, in addition, through Sir Thomas Storey it had given the Storey House for 40 trained feeble-minded girls at a cost of between £7000 and £8000. Since it was started in 1864 no less than £467,000 had been given by men and women living in the seven northern counties. The report stated that a large number of patients suffered from tuberculosis, but Sir J. T. Hibbert hoped that by the aid of benefactors and out of their own funds they would make some attempt to deal with these patients. Dr. W. S. Paget-Tomlinson of Kirkby Lonsdale emphasised the importance of definite action being taken to deal with tuberculous cases and suggested the erection of a small wooden annexe or bungalows, towards which, if the idea were taken up, he would subscribe £100. Dr. W. W. Wingate-Saul of Lancaster also announced that he would erect a chalet in the asylum grounds for the treatment of tuberculous patients. This generous action by members of our profession was much appreciated by the meeting The after-care of those who have training at the asylum has been a matter causing anxiety. It is difficult for a person of feeble intellect to find employment after leaving the institution and some have had to return to the workhouse they came from. At the luncheon the Earl of Derby said there was a great want of provision for the care of the feeble-minded and an effort was being made to rouse the Government to a sense of the importance of the question. "Custodial asylums were much needed and also homes for those who had undergone training but had no friends able or willing to look after them " In the census of 1901 the number of imbecile or feeble-minded persons was returned as 48 882, or one for every 665 of the population. In the United States the proportion is said to be one to every 600 of the population.

The Use of Patent Medicines.

On Sept. 23rd Mr. E. A. Gibson, the Manchester coroner, concluded an inquest on a child, five months old, who had been treated by the parents with a quack medicine called "Jackson's febrifuge." Dr. Ashby made a post-mortem examination and found that the child had broncho-pneumonia. After seeing the analysis of the medicine he said that it would do no good and no harm, but would take the place of more efficient remedies. Mr. Estcourt, the city analyst, "found that it contained ammonium chloride, potassium chloride, potassium sulphate, sodium sulphate, sugar, ipecacuanha, camphor, cloves, ginger, liquorice, and probably rhubarb, and a small quantity of chloroform"—a fine sample of poly-pharmacy. Dr. Ashby, in reply to a question, said "he was very much surprised to learn that last year 2184 gallons of the medicine, equal to 87,360 shilling bottles, had been sold." The defendant's solicitor said: "It is used by a number of members of the Manchester city council, ministers of religion, and magistrates." Dr. Ashby: "Ministers of religion will do anything. I don't know about city councillors." It is curious that among the former class there is so strong a leaning to quackery in all its forms. The coroner said there was nothing connecting either the febrifuge or Jackson with the death of the child but that death was probably due to lack of treatment owing to the ignorance of the parents and their reliance "on this worthless stuff." Upon this summing up there followed the verdict of "Death from natural causes." The coroner added that it was a public misfortune that such an article as "Jackson's febrifuge" should be in the market and have such a wide circulation.

Bolton Infirmary.

The honorary treasurer of the Bolton Infirmary has received a cheque from the chairman of the Hospital Saturday Fund for £2780. This is a little more than last year's contribution.

A Faith-Healer.

The case of a man charged with wilfully ill-treating and neglecting his daughter was tried at the City Sessions on Oct. 1st. It illustrates the marvellous absence of commonsense displayed by some of the fanatical followers of the so called Dr. Dowie. The child on Sept. 3rd fell down some steps and broke her right collar bone. On returning home the father was told of the accident and the mother wished to send for a medical man, but he would not allow it and instead knelt down and prayed. So things went on, though the mother again tried to get his permission to take the child to a medical man, till Sept. 8th when he allowed her to be taken to a druggist. The druggist said that the bone was broken and advised her being taken to the infirmary. But the father would not allow this. On the 11th an inspector of the Society for the Prevention of Cruelty to Children interposed and the father took the child to the place where his sect held their meetings, apparently to enable the elders to pray over her. It was not till Sept. 21st that by an order of the court an inspector of the society took the child and she was properly attended to. The defendant gave evidence on oath and said that one of the principles of his Church was that "all cures were effected by means of faith and prayer." He is said to have sent a telegram to "Dr. Dowie" at Zion City asking for his prayers but had had no reply. If he *prayed without replying* "it was quite certain," as the prosecution said, "that the prayer was not answered" till the child was medically attended. It is curious that in these days anyone can believe the pretensions of Dr. Dowie or of people like him, but this man no doubt believes in him. He said he had believed in [illegible] 18 years of age he heard [illegible] —about the medical pro- [illegible] *Afterwards he took up* hydropathy. "Now he had got the divine truth—a truth of God " He is not alone in his notions, for several witnesses expressed their belief in "faith healing." The recorder said the question was, had the defendant wilfully neglected the child so as to cause her unnecessary suffering or to be a disadvantage to her health? The jury found that he had and he was sent to gaol for a month with hard labour. *Probably from his fellow fanatics he will receive* honour and glory as a martyr and will retain his faith, but society, and more particularly children, who are the chief sufferers, must be protected from the consequences of pernicious doctrines leading to cruelty, even if they are held honestly.

Oct 6th.

LIVERPOOL.

(FROM OUR OWN CORRESPONDENT.)

University of Liverpool: Opening of the Winter Session of the Medical Faculty.

THE first public function associated with the University of Liverpool took place on Oct. 1st, when, in the Arts Theatre of the University buildings, the winter session of the medical faculty was opened by a distribution of prizes by Sir Dyce Duckworth. In the absence of the chancellor (the Earl of Derby, K.G.), the vice-chancellor (Principal Dale) presided over a large and representative assembly. As is customary on such occasions academical costumes were worn. Those present included the Lord Mayor, the Lord Bishop of Liverpool, Sir William M Banks, Professor Bradley (Oxford), Major Ronald Ross, C B., F.R.S., late I.M.S., Professor R. W. Boyce, F.R.S, Professor Moore (dean of the medical faculty), and Dr. James Barr. At the onset of his introductory address, as your readers will have seen, Sir Dyce Duckworth remarked that they must try to imagine the feelings of one who, having been born in Liverpool and having begun his preliminary studies in the humbler days of the Liverpool School of Medicine, returned after the lapse of so many years to take part in a ceremony memorable as that truly was that day, when they formally met for the first time as the newly constituted faculty of medicine of the University of Liverpool. He offered his warm congratulations to his fellow citizens on their wisdom and energy in seeking and securing the charter for their University. Lancashire men generally knew what they wanted, and what they wanted they commonly contrived to get; and, further, with what they got they were proverbially generous. Sir Dyce Duckworth made a complimentary allusion (for their prescience and untiring energy in promoting not only the welfare of that faculty but the establishment of the University itself) to his fellow graduates, Sir William

Banks, Dr. A. Davidson, Dr. Richard Caton, and Mr. Edgar Browne. He paid them this small tribute without any disparagement to the loyal and generous support afforded by others in the school, or to the munificent benefactors amongst their wealthy and enlightened fellow citizens. The Lord Mayor proposed a vote of thanks to Sir Dyce Duckworth for his able address, which was carried with acclamation.

Oct. 6th.

WALES AND WESTERN COUNTIES NOTES.

(FROM OUR OWN CORRESPONDENTS.)

Monmouthshire Health Report.

ALTHOUGH the Monmouthshire county council has not thought fit to appoint a county medical officer of health there has been issued for several years past an annual "review of the general sanitary condition of the county" founded mainly upon the annual reports of the district medical officers of health, with abstracts of, and comments on, those reports by the sanitary committee of the county council. The review for 1902 is signed by Dr. T. H. Redwood, the chairman of the sanitary committee, who is also medical officer of health of Rhymney urban district, and among the members of the sanitary committee are other district medical officers of health. The birth-rate for the county during 1902 was 17·8 per 1000 and the death-rate was 17·8 per 1000. The lowest death rate was 11 per 1000 in Risca and the highest was 22·8 in Tredegar. The infantile mortality rate for the county was 142 per 1000 births; in Pontypool this rate was as low as 74 per 1000 births and in Abergavenny as high as 209 per 1000. The zymotic death-rate was 2 8 per 1000 in the county and in Bedwellty it was 6·9 per 1000. Monmouthshire is well known to have a low mortality from tuberculosis; it is of interest therefore to learn that in 1902 the death-rate from this disease was 0 74 per 1000; in the urban districts, however, the rate was 0 61 per 1000 and in the rural districts it was 1 per 1000. There are still ten of the 25 sanitary districts without isolation hospitals and the sanitary committee advises the county council to insist on the provision of means of isolation in these districts. There is only one district (Abercarn) provided with a steam disinfector; it is not at all surprising, therefore, to find that diphtheria and scarlet fever were prevalent in the populous urban districts during 1902. In Bedwellty, with a population of 11,000 persons, there were 203 cases of diphtheria, and in Ebbw Vale, where there is a population of over 23,000, there were 269 cases of scarlet fever. There does not appear to be any refuse destructor in the whole county, household refuse being disposed of on land or collected on tips. The sewage from most of the districts discharges into adjoining rivers, though in one populous part that is known as the Western Valleys there is now being constructed a main trunk sewer which will terminate in the Bristol Channel.

The Cost of Pauperism.

The statistical returns recently issued by Mr. E. B. Wethered, Poor-law inspector to the Local Government Board, are of considerable interest and show that in 34 of the 44 unions in his district there was an increase in the cost of maintaining the poor during the year ending Lady-day, 1903, compared with the previous 12 months, although the number of persons actually relieved on the first day of January, 1903, was in many instances lower than on the same date in 1902. In Gloucestershire the cost was £135,000, compared with £129,000 in the previous year, and in Bristol the cost was £66,700 compared with £64,000. The cost per head of the census population varied in Gloucestershire from 3*s.* 2*d.* and 4*s.* in the Gloucester and Bristol unions to 5*s.* 7*d.* and 5*s.* 10*d* in the Cirencester and Wheatenhurst unions.—At the annual conference of the Plympton union parish council and parish association held at Yealmpton (Devon) on Sept. 30th Mr. Preston Thomas, inspector to the Local Government Board, stated that when he first went to the western district in 1896 he found that the Poor-law had not been very much looked into and he therefore took the course of continually bringing the subject before the boards of guardians. There were now 10,000 fewer persons in receipt of relief and upwards of £20,000 less spent in out-relief than when he first went to the district.

Glamorganshire Education Committee.

Dr. T. H. Morris, surgeon to the Tylorstown collieries in the Rhondda Valley, has been elected chairman of the education committee of the Glamorganshire county council.

Rent of Cottages in Newport.

It is stated on the authority of the local trades council that two roomed tenements (of which there are not many) may be rented in Newport (Mon.) for 3*s.* 6*d.* per week, four-roomed cottages for 5*s.* 9*d.* per week, and larger cottages from 6*s.* 6*d.* to 10*s.* 6*d.* per week. Artisans are said to pay 25 per cent. of their wages in rent and labourers 35 per cent. During the past six years rents have increased in Newport about 2½ per cent.

A Coroner on the Holding of Inquests.

On Sept 28th the coroner for Haverfordwest held an inquiry into the cause of death of a man, aged 59 years, who arrived in Haverfordwest from Llanelly on Sept. 25th and died on the following day. The medical man who was called to see him gave a death certificate, stating the causes as pleurisy and peritonitis, but on Sept. 28th a solicitor, on behalf of the relatives, telegraphed from Llanelly to the coroner demanding an inquest and post-mortem examination and adding that the deceased had upon him a considerable sum of money which had disappeared. The coroner therefore held an inquest and ordered a post mortem examination which confirmed the diagnosis set forth in the death certificate. The jury returned a verdict of "Death from natural causes" and the coroner severely condemned the hasty action of the relatives, saying that the solicitor should have gone to Haverfordwest and made inquiries before causing an inquest to be held.

Enteric Fever at Merthyr Tydfil

At the meeting of the Merthyr Tydfil urban district council, held on Sept. 30th the medical officer of health, Mr. D. J. Thomas, reported that there were 66 cases of enteric fever under treatment at the isolation hospitals. Owing to pressure of work upon the medical officer of health the council decided to provide him with an assistant for one month.

Bristol University College.

The inaugural lecture of University College, Bristol, was delivered on Oct. 5th by Professor R. M. Ferrier who gave an interesting address on Steamships—Past, Present, and Future. Mr. P. J. Worsley, J.P., presided and there was a large attendance Professor Lloyd Morgan, in proposing a vote of thanks to the lecturer, remarked that undoubtedly if England were to keep her high position they must rise to the responsibility of their position intellectually and they must do their best for the higher education such as for years they had striven to give in the University College of Bristol—the embryo, he hoped, of the university for the west of England that was to come.

SCOTLAND.

(FROM OUR OWN CORRESPONDENT.)

Is Insanity Increasing?

DR. J. CARSWELL, certifying physician in lunacy to the Glasgow parish council, has issued his annual report on the certification of lunatics for the year ended May 15th, 1903. He states that 840 applications were made to the inspector of poor on behalf of persons supposed to be insane. Of these, 549 were certified as insane while 291 were not certified; but a very important fact is brought out showing that of the uncertified cases 242 (the majority of whom were men) were treated in the temporary observation wards at Barnhill; 193 of these were discharged recovered, the patients being, as a matter of fact, nearly all "alcoholics," while only 36 were subsequently removed to an asylum. There is sufficient evidence here to show the advantage of such wards and there can be no doubt of the wisdom of the parish council in making further provision for these unconfirmed and incipient cases of insanity in the new mental hospital which is a part of one of the two general district hospitals at present being erected in Glasgow. This mental hospital is the first of the kind in the kingdom and will supply for Glasgow a means of treating incipient cases without the necessity of certifying the patients as insane and sending them to an asylum. The number of cases certified as insane this year—549—is exactly equal to the average number for the three years 1901–03 and represents as certified 65·4 per cent. of the total applications; 162 had suffered from previous attacks of insanity and the remaining 337 represent the actual number of persons who became insane for the first time during the year. This is 19 less than last year and the proportion per 100,000 of the population is 65·5 compared with 70 last year. This is taken as indicating a satisfactory movement as regards the actual production of insanity. Dr. Carswell further expresses his views very strongly, and they are new, regarding the general impression that there is an increase of insanity. The steady increase in the numbers resident in asylums would indicate that there was such an increase but he holds that while there are more registered lunatics there is not necessarily more insanity. He produces tables showing the age and sex distribution of first attacks of insanity and the rate of production per 10,000 persons living at each age period during the years 1901–03, examination of which proves (1) that the rate of production at ages below 45 is tolerably constant, that it is almost identical for males and females, and that it shows no tendency to increase (on the contrary, during last year there was a decided decrease); and (2) that there is a decided increase in the rate of production above 45 years of age and this most marked in males. By reference to the fortieth annual report of the Commissioners in Lunacy Dr. Carswell shows that throughout Scotland during the ten years period 1887–96 some influences had been in operation which had the effect of increasing the number of admissions to asylums at ages above 40 years at a much greater rate than at ages between 20 and 40 years and had the further effect of changing the age period which produced the highest number of admissions (omitting the periods under 20 and over 70 years) per 100,000 of population from 30–40 to 40–50. The figures relating to Glasgow reveal the operation of those influences common to the whole of Scotland though varying in their effects according to local circumstances. These influences are connected with the social and the industrial conditions which have prevailed during the last half century, associated as they have been with the great philanthropic movement which has so profoundly influenced local government in all its branches. During the young and active period of life the industrial classes in Glasgow have practically no struggle for existence. Employment for them is abundant and with prudent habits their health, which is their capital, is almost completely protected by public authority. Consequently the production rate of insanity during the earlier periods of life is not increasing and is not too high relatively to existing conditions. The real struggle for existence among the working and labouring classes only begins in middle life and towards later years. The competition then begun finds the drunken and incompetent unequal to the new conditions and insanity is one of the forms in which such incompetence is expressed. A person who cannot find work on account of mental deficiency or disorder becomes a financial burden upon some one, and as the increasing competition makes it increasingly difficult for persons so afflicted to find employment the tendency is to take advantage of asylums for their custodial care. Asylums being rate-supported, it is only reasonable that the public should increasingly use them for the care of persons who might be otherwise cared for under easier and simpler industrial and domestic conditions. Whatever explanation may be adopted regarding the causes that underlie the production of insanity, such explanation must take account of the stability of the sex and age distribution of cases under 60 years not only in Glasgow but all over Scotland, and it would seem that the above explanation fulfils this condition. On the other hand, while intemperance, for example, is a factor of great importance in the question of the cause of insanity, yet such a cause coming into operation would show considerable fluctuations in the sex and age distribution over a series of years, the very thing which does not occur; so with the other so-called primary causes. Dr. Carswell's conclusion, then, is that certain influences, mainly social and economic, have been in operation during a period of over 50 years which have had the effect of improving the condition of the people and at the same time of filling the asylums. The contradiction is only apparent and the increase is an increase of lunatics under public control but not an increase of insanity. An obvious practical conclusion drawn is that existing conceptions of the character of the accommodation required for the care of the insane stand in need of revision. The recovery-rate of asylums has gone down coincidently with the changes in the character of admissions. There is consequently an accumulation of incurable lunatics and the need that now exists for merely custodial care for a considerable proportion of the patients is more apparent than when the existing asylums were built.

Oct. 6th.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

The Local Government Board and the Granard Guardians.

THE quarrel between the Granard board of guardians, their medical officer, and the Local Government Board of Ireland, maintains its professional interest. A sealed order removing the master of the workhouse was duly received with a letter calling upon the board of guardians to take steps for the appointment of a suitable person in his stead. After a long discussion a motion was passed unanimously that he be appointed to the temporary mastership of the workhouse until the next meeting on Oct. 5th. On that day a letter was read from the Local Government Board authorities requesting the guardians to make suitable arrangements for the discharge of the duties of master of the workhouse and pointing out that if the guardians persisted in retaining the late master they would themselves feel constrained, under the powers vested in them, to nominate a master. The guardians forthwith passed a motion to "hold on" to the master "no matter what the cost might be, as they had strong opinions he was not getting fair play."

St. Vincent's Hospital, Dublin.

The address introductory to the medical session was delivered at St Vincent's Hospital, Dublin, on Oct. 6th by Mr. R. F. Tobin who chose for his subject the present position of the Irish Poor-law medical service. The lecturer could not have selected a topic of more vital importance to Irish medical men. The claims of the Irish Poor-law medical service are urgent, as all your readers know.

Some Questions about the Public Health of Belfast.

Since the publication of Professor Lorrain Smith's "Report on the Occurrence of Typhoid Fever in Belfast" considerable discussion has taken place in the city upon the many matters of vital importance, medically and socially, which have been brought into prominence. The chairman of the water commissioners has submitted his criticism[1] and on Oct. 1st the local papers published a manifesto from the chairman of the public health committee who, apart from several minor details, is generally in agreement with the results and recommendations embodied in Professor Smith's report. Speaking of hospital accommodation the chairman of the public health committee says that his committee for the past 15 years has been labouring to convince the corporation of the necessity for hospital accommodation for the respectable poor of Belfast who do not wish to have the stigma of pauperism attached to their names. Year after year this subject has been brought forward and has met with very strenuous opposition in the most unexpected quarters, and it is only within the past year that all the difficulties of the case have been overcome and the contract signed for the erection of a first-class infectious diseases hospital in one of the healthiest sites in Ireland (Pur [illegible] ago, [illegible] shou [illegible] in. [illegible] the c. [illegible] any time during those 15 years the chairman of the public health committee, finding that the recommendations of his committee were not attended to by the rest of the corporation, had resigned his post and had given his reasons to the public, his position would have been indorsed and years ago Belfast would have been provided with a modern fever hospital. In the meantime the chairman of the public health committee appeals to the guardians to convert the workhouse fever hospital into a district hospital—a policy that seems to clash with his statement which I have quoted that hospital accommodation is particularly required unconnected with the stigma of pauperism. The guardians declined when first asked by the public health committee to take any action in the matter. Will they take a more public-spirited course now? There seems to be little real attempt made to face any difficulty or emergency in public health. Belfast at the present time has not an available bed for persons of the middle classes suffering from infectious disease who are willing to pay for their reception, and this anomalous state of affairs will continue for three years until the new hospital is ready. To meet the difficulty the public health committee might have taken over the old Royal Hospital which was offered to it or it might have advised the erection of temporary iron buildings at Purdysburn as it was compelled to do for cases of small-pox. In taking either of these courses the committee would have satisfied public opinion but instead of this it intends to ask the guardians to reconsider the idea of a conversion of the workhouse fever hospital. Will this course remove the reproach from Belfast of having "the highest typhoid death-rate of any city in the world"? It is announced that the public health committee is still considering Professor Smith's report and will bring it before the council. There will be discussion, but will it be followed by action?

---

[1] THE LANCET, Oct. 3rd, 1903, p. 983.

The Lord Mayor of Cork and the General Superintending Medical Officer of Health.

Some weeks ago vacancies occurred for two sub-sanitary inspectors in Cork and it was decided that the candidates should be examined by Mr. D. D. Donovan, general superintending medical officer of health, and by Mr. O'Keeffe, executive sanitary officer. The report of the examiners showed that one of the three candidates had scored 55 marks out of a maximum of 75 and was far ahead of the other two. The public health committee, however, with the report of the examiners before it appointed the two men who had comparatively failed in the examination. When the minutes of the committee came before the town council there was an animated discussion and the Lord Mayor strenuously indorsed the action of the committee on the grounds that the examination was the merest farce, a statement which he repeated in emphatic terms. However, a large majority of the council viewed things differently from his lordship and the candidate who had been successful in the test was very properly appointed to one of the vacancies. The Lord Mayor's references to the examination have been very severely criticised and have provoked much indignation, especially as Mr. Donovan is a very active medical officer of health and enjoys the esteem and confidence of his fellow citizens. On Oct. 3rd there was a meeting of the medical profession to consider the matter when the following motion was passed unanimously:—

> That we, the members of the Cork medical profession, view with the greatest indignation the unjust observations which were recently made in public by the Lord Mayor with regard to the examination held for the post of sub sanitary officer by our medical officer of health, Dr. D. D. Donovan, and we wish to express our entire confidence in the skill and integrity of our medical officer of health and in the manner in which he has on all occasions faithfully discharged his duties.

Oct. 6th.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

After the Plague.

NOW that the epidemic is quite over the sanitary administration has begun to be severely criticised with the object of profiting in the future by the experience which it has just undergone. The chief criticism is concerned with the lazaretto at Frioul in which passengers coming by ships from foreign parts and suspected of plague are kept. As soon as the recent epidemic was notified the municipal administration very naturally wished to isolate its suspects in this lazaretto which is situated upon an isolated island where surveillance is easy and which was erected for this very end. To the surprise of everybody the sanitary authorities refused to receive these patients, declaring that the Frioul lazaretto was entirely under the maritime authorities and that its object was the reception of patients before their landing on French soil, and, moreover, that the establishment had not sufficient room to receive patients from the town and that means for revictualling (*ravitaillement*) were scanty. That was the reason why the municipal administration of Marseilles had to lodge its plague patients in some buildings kindly lent for the purpose by M. Salvator, which were transformed into a special hospital. It is very probable that the lazaretto of Frioul, which has already been the subject of lively criticism at the sittings of the Academy of Medicine, will in a very short time be discussed again. On the other hand, the town of Marseilles has appealed to the Minister of Foreign Affairs to ask that the divers Powers which have just put into force severe quarantine measures against merchandise coming from Marseilles should recall these measures. The Marseilles municipality argues that these measures are due to an exaggerated view of the danger and are apparently inspired by commercial rivalry which has seized upon the occurrence of plague as a pretext. Italy, Spain, Greece, Turkey, and Uruguay have signalised themselves by formulating very severe quarantine laws. As it appears that there is no doubt that the Marseilles plague was brought from Constantinople this seems somewhat odd.

The Old School of Medicine and the Old Academy of Medicine.

Some years ago the municipal authorities of Paris bought up the ancient buildings which belonged to the first school of medicine founded in Paris. These buildings had been scheduled as *monuments historiques* and it was intended to turn them into a museum of medicine and surgery. However, this idea had to be given up, for when the repairs were begun it was found that the buildings were on the point of collapsing and that it would be dangerous for the public to visit them. So the Paris Society for the Protection of Ancient Buildings (Commission du vieux Paris) is going to inquire into the possibility of preserving a portion which seems capable of repair or else of pulling down the whole structure. The old buildings of the Academy of Medicine have also been put into the restorer's hands and they have found how singularly insanitary was the small hall where the council used to meet. On the carpet being taken up no less than ten others were found, one on the top of the other underneath the first. They were all very old and thick with dust. No very vivid imagination is required to conceive of the number of microbes existing therein.

Obituary.

Dr. Fochier, professor of clinical obstetrics in the Lyons Faculty of Medicine, died suddenly on Oct. 2nd in the rector's antechamber.

Public Health of Madagascar.

At the meeting of the Academy of Medicine which was held on Oct. 6th M. Kermorgan read a long report upon the sanitary work which has been accomplished in Madagascar by General Gallieni. Once more are evident the admirable results which can be arrived at when an energetic administrator who is given a free hand works with a will. When General Gallieni arrived in Madagascar the island was decimated by malaria, alcoholism, small-pox, and syphilis. General Gallieni set to work with vigour and has founded a native school of medicine, a Pasteur institute at Tananarivo, a vaccine farm at Diego-Suarez, 20 hospitals containing 1300 beds, four lazar houses containing 1200 lepers, and two more in process of construction. Besides these, stations where medical relief can be obtained are being multiplied. To these works must be added the colonial hospitals and various institutions supported by private charity, one maternity hospital, two lazar houses for 900 lepers, and two ordinary hospitals. The total expenses for sanitary service during the year 1902 amounted to nearly 1,000,000 francs, which sum has been partly obtained by a tax of three francs per head of inhabitants, called the medical aid tax. The number of patients in the ordinary hospitals was 11,134, the number of lepers in the lazar houses was 2540, the number of vaccinations performed was 150,056, and 749,485 patients obtained advice and medicine. Owing to the admirable exertions the death-rate has gone down and the birth-rate has gone up in a notable fashion. Small-pox has almost completely disappeared from the central table-land, although it still exists in some provinces. Severe measures have been taken to put down alcoholism and no native is allowed to keep a drink shop. Leaflets have been distributed and medical advice with medicine has been given with the result of already diminishing syphilis in a very marked manner. The Governor is actively engaged with the question of leprosy. The central table-land contains over 4200 lepers, of whom 2540 are in the various lazar houses while some 1800 live with their families or wander from place to place. The new lazar houses which will be ready this year will reduce this number to 800. When it is remembered that three out of every 1000 inhabitants of Madagascar are lepers it will be seen that the time for action had arrived.

The Inoculation of Syphilis in the Monkey.

Three chimpanzees, two females and one male, have been successfully inoculated with syphilis by M. Roux and M.

Metchnikoff The first female inoculated has died, not from syphilis, but from a throat affection characterised by the formation of membrane which was, however, not true diphtheria. The disease was contracted from another monkey which is also dead The syphilitic lesions were quite characteristic and included chancres, secondary rashes, and mucous plaques, together with the typical glandular swellings Doubt has been thrown on the value of these experiments, but it would appear to be certain that if a chimpanzee can be infected with syphilis by inoculation it will be able to be proved that if inoculation with attenuated virus does not infect the chimpanzee it will also not infect human beings, and such an experiment has been impossible to make heretofore.

Oct 6th.

Medical News.

UNIVERSITY OF GLASGOW.—The following candidates have passed the first professional examination for the degrees of Bachelor of Medicine (M B) and Bachelor of Surgery (Ch B.) in the subjects indicated (B , botany ; Z , zoology ; P , physics ; C , chemistry) :—

Robert Govan (Z ,

C *), James Robertson Mitchell (Z ,* C) Hugh Walker Muir (B), Robert Charles Muir (B), Archibald Campbell Munro (B , P *), Arthur Alexander Murison (C) Isaac Papiermeister

The following have passed the second professional examination for

Bachelor of

anatomy ; P

peutics) :—

*George Allison Allan (M *) George Victor Anderson (P)* James Henderson Baird, B A (M), Hugh Barr (M) George Duncan Morrison Beaton (A P), George Thomson Bogle (A), Charles Burns (A.), Donald Livingston Carmichael (A), John Paterson Carmichael (M) Charles Game Angus Chislett (P , M), Donald Clark (P) Thomas Goodall Copestake (A), Andrew Donaldson Cowan (P), Harold Windley Dempster (A.) John Shaw Dunn M A (M), Eric John Dyke (M), Hamilton William Dyke (M), Edward John Fitzgerald (A , P), Thomas Henderson Forrest (P), Joseph Glaister (A , P), Alexander Graham B Sc (M) John Isdale Greig M A (A , P), William Grier (M), Charles Francis Dyer Hammond (A , P ,* M), John Hammond (M), Saul Hyman Harris (A), James Duncan Hart

The following have passed the third professional examination for the degrees of Bachelor of Medicine (M B) and Bachelor of Surgery (Ch B) in the subjects indicated (P , Pathology , M , Medical Jurisprudence and Public Health) —

Scott Campbell Adam (P , M), Andrew Blair Aitken (P), Henry Graeme Anderson (M) James Richard Sumner Anderson (P), Robert Daniels Bell M.A (P , M) Thomas *Brodie (P , M)* Robert Buchs William Davidson (P) Thomas), Hugh M'Millan Donaldson (M), Hugh Harvie Fulton (M), M) George Munn Gray (M *), (P , M) Archibald Yuill Hutchi James Rutherford Kerr (P , M) *l Cabe (M) Donald* Carmichael M (P) Tom Duncan M'Ewan (M) n M Farlane (M), Alexander St) Milne M'Intyre (M), Charles Gordon Mackay (P , M), Roderick MacLeod (M), James Marshall (P , M) *David Robertson Mitchell (M), Gavin* Denholme Muir (M), John Murdoch (P , M) Frank Anderson Murray (P , M), Thomas Orr (M) Howard Henderson Patrick Pollok (P), Andrew Murdoch Rae Richmond (M), John ert Wilfrid M), James David Alexand Watson P)

Women — (M), Ethel L rgaret Walker), and Annie May Yates (P , M)

* Passed with distinction in the subjects indicated

MEDICAL MAGISTRATE —Mr Arthur C. J Wilson has been placed on the commission of the peace for the West Riding of Yorkshire

DEATH OF A CENTENARIAN —John Lenin, who was 102 years of age, died recently at St Austell (Cornwall) Workhouse and the master reported the fact to the guardians at their meeting on Oct 2nd.

THE ROYAL COLLEGE OF PHYSICIANS OF IRELAND. —At a stated meeting of the College held on Oct 2nd Mr Thomas Greenhalgh, L R C P Irel , 1868, was admitted to the grade of Member of the College

LITERARY INTELLIGENCE.—The Walter Scott *Publishing Company, Limited, are just adding* a notable work to their "Contemporary Science Series"—namely, "Morals A Treatise on the Psycho Sociological Bases of Ethics" It is a translation of Duprat's famous book, "La Morale," made by W J Greenstreet, M A., headmaster of Marling School

ÆSCULAPIAN SOCIETY.—A meeting of this society was held on Oct. 2nd, when Dr Leslie Durno delivered the presidential address on "A 25 Years' Postgraduate Course in Sepsis and Antisepsis" He said that Lord Lister first declared that fermentation in wounds was due to the presence of bacteria and later prevented that change by the use *of carbolic acid solution Noting the* changes that had taken place in the methods of antiseptic dressings from the early days to the present time, Dr Durno reviewed the various agents by the use of which power over organisms was exercised, classing them as (1) exclusive ; (2) inhibitive ; (3) attenuative ; (4) neutralising of ptomaines ;

(5) mechanical; (6) dehydrating; (7) oxygenating; and (8) deoxygenating. The various infecting sources were reviewed and mention was made of several processes in the treatment of wounds, of instruments, and of the hands. The address was heartily applauded.

DEATHS OF EMINENT FOREIGN MEDICAL MEN.—The deaths of the following eminent foreign medical men are announced:—Dr. Richard Pott, professor of children's diseases in the University of Halle.—Dr. M. D. Chaussoff, professor of anatomy in the University of Warsaw.—Dr. James F. Hibberd, formerly professor of physiology and general pathology in the Ohio Medical College, Cincinnati. —Dr. Marenghi, *privat-docent* of general pathology in the University of Pavia.

PRESENTATIONS TO MEDICAL PRACTITIONERS.—Mr. John Wyatt Pratt, M R.C.S. Eng., L R C.P. Edin., L S.A., who has practised for several years at Wiveliscombe, Somerset, has been presented with a purse containing £98 as a mark of respect and esteem by his friends and patients in the district.—The Newton Abbot (Devon) division of the St. John Ambulance Brigade on Sept. 28th celebrated its team's success in winning the challenge cup offered as a prize to be competed for by the ambulance teams of Devon and Cornwall at Redruth on Sept. 26th, and after dinner Mr Richard Henry Grimbly, M.R.C.S. Eng., L.S.A., was presented with a silver-mounted cane in appreciation of his honorary services as instructor to the successful team.

GLASGOW SOUTHERN MEDICAL SOCIETY.—The first meeting of this society for the session 1903-04 was held on Oct. 1st, when the following gentlemen were appointed office-bearers:—Sir J. Halliday Croom, honorary president; Dr. Thomas Richmond, president; Dr. J. Fraser Orr and Dr. A. E. Maylard, vice-presidents; Dr. Thomas Forrest, treasurer; Dr. Andrew Wauchope, secretary; Dr. James Weir, editorial secretary; Dr. G. H. Edington, seal-keeper; extra members of council—Dr. M. Dunning, Dr. R. T. Halliday, and Dr. Kelly; court medical—Dr. D. Macgilvray, Dr. H. L. G. Leask, Dr. T. K. Monro, Dr. John Stewart, and Professor R. Stockman. Dr. C. E. Robertson was reappointed a governor of the Victoria Infirmary. It was arranged that the annual dinner should be held on Oct. 15th.

THE VOLUNTEER AMBULANCE SCHOOL OF INSTRUCTION.—The winter session of this school commenced on Oct. 5th at the headquarters of the London Rifle Brigade which have kindly been placed at the disposal of the senior medical officer by Lieutenant-Colonel Lord Bingham. There was an excellent muster of all ranks in both the advanced and junior classes and Brigade-Surgeon-Lieutenant-Colonel P. B. Giles announced that no more would be taken in either class after the next lecture. The officers who have been selected to take part in the instruction are Surgeon-Major W. Culver James, Surgeon-Major R. R. Sleman, Surgeon-Captain E. M. Callender, Surgeon-Captain E. W. St. Vincent Ryan, Surgeon-Captain C. S. de Segundo, Surgeon-Captain A. D. Ducat, and Surgeon-Captain J. A. Masters. The competition for the challenge bowl presented to the school by the late Surgeon General J. B. Hamilton will take place on Dec. 7th.

CHARING CROSS HOSPITAL.—On Oct. 1st Sir Charles Wyndham presented the prizes won by the students at the hospital during the past year and delivered an address, an abstract of which will be found in another part of our present issue. The dean, Mr. Herbert F. Waterhouse, in his annual report stated that the hospital was completely closed for extensive building operations on July 18th and would reopen on Oct. 5th when it would be found that a complete transformation had taken place and that Charing Cross would in a few months, when all the buildings were completed, have with its convalescent home a service of 300 beds and a hospital as nearly approaching perfection in construction as was possible considering its position in the very centre of the greatest city in the world. It is understood that on Oct. 12th the governors of King's College Hospital will be called upon to decide whether or not their hospital shall be moved to the south side of the Thames. If, as seems almost certain, their decision be in the affirmative, there will then be no general hospital nearer to Charing Cross eastwards than St. Bartholomew's. The bulk of the patients who now seek advice at King's College will therefore probably go to Charing Cross Hospital and this, though throwing a further strain on the resources of the hospital, will greatly increase its usefulness as a field of clinical observation and research.—The following entrance scholarships have been awarded: The Epsom scholarship (100 guineas) to Mr. N. G. H. Salmon, the Livingstone scholarship (100 guineas) to Mr. R H. H. Jolly, and a Universities scholarship (72 guineas) to Mr. W. D. Keyworth. Entrance scholarships have also been awarded to Mr. P. E. Stibbe (60 guineas) and to Mr. C. H. F. Atkinson (30 guineas).

UNIVERSITY OF CAMBRIDGE.—Mr. Howard Marsh, the new Professor of Surgery, was on Oct. 5th elected surgeon to Addenbrooke's Hospital.—The office of assistant surgeon is vacant by the resignation of Mr. Hubert Higgins. —Mr. R. C. Punnett, of Gonville and Caius College, has been appointed Demonstrator of Comparative Anatomy.—The chair of Physiology is vacant by the resignation of Sir Michael Foster, K.C B., on Sept. 30th.—Under the will of the late F. J. Quick, B.A., of Trinity Hall, his trustees are directed, when several conditions are fulfilled, to transfer to the University an estate which eventually, when several annuities have determined, will amount probably to £70,000, "for the furtherance of study and research in the sciences of vegetable and animal biology."

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward to THE LANCET *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, such information for gratuitous publication.*

BALLANTYNE, T., M.B., Ch.B. Glasg., has been appointed Junior House Surgeon to the Blackburn and East Lancashire Infirmary.

BRIGGS, WALTER, M.B., Ch.B. Vict., has been appointed Senior House Surgeon to the Blackburn and East Lancashire Infirmary.

BRUCE, R. H. G., M.B., M.S. Aberd., has been appointed Certifying Surgeon under the Factory Act for the Friockheim District of the County of Forfar.

DUNCAN, A., M.B., M.S. Glasg., has been appointed Certifying Surgeon under the Factory Act for the Moorfields District of the County of Antrim.

EDWARDS, R. T., M.R.C.S., L.R.C.P. Lond., has been appointed House Surgeon and Secretary to the Aberystwyth Infirmary.

HARDY, FRANCIS A., M D., C M. Edin., has [illegible] Officer and Public Vaccinator for the [illegible] Newark Union and Medical Officer and [illegible] Leadenham District of the Shelford Union.

HARRISSON, E. H, M B., M.C., B.A. Cantab., has been appointed Certifying Surgeon under the Factory Act for the St. Neot's District of Huntingdon.

KENNEDY, A. D., M.B., Ch B. Glasg., has been appointed Certifying Surgeon under the Factory Act for the Ballachulish District of the County of Argyll.

ROBERTSON, J. MCGREGOR, M.B., Ch.B. Glasg., L.M., has been appointed Assistant Master of the Coombe Lying-in Hospital, Dublin.

THOMAS, EDWIN R., L R C.P. & S. Edin., L.F.P. & S. Glasg., has been appointed Medical Officer of Health of the Borough of Beaumaris.

PEARSE, T. FREDERICK, M D., F.R.C.S. Eng., D.P.H. Camb., M.R.C.P. Lond, has been appointed by the Government of Bengal Lecturer on Hygiene at the Medical College, Calcutta.

POOLE, J. S., M.D. Canada, has been appointed Clinical Assistant to the Chelsea Hospital for Women.

UNWIN, W. H., M.B. Lond., F.R C.S. Eng., has been appointed Clinical Assistant to the Chelsea Hospital for Women.

WHITELEGGE, B. A., M.D., C.B., His Majesty's Chief Inspector of Factories, has been appointed President of the Epidemiological Society.

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement (see Index).

BILLINGSGATE HOSPITAL MISSION.—House Surgeon (Lady).

BRIDGNORTH AND SOUTH SHROPSHIRE INFIRMARY.—House Surgeon. Salary £100, with board and lodgings.

CAMBRIDGESHIRE, &c., LUNATIC ASYLUM, Fulbourn.—Second Assistant Medical Officer, unmarried. Salary £120, with board, lodging, and attendance.

CARDIFF INFIRMARY.—Assistant House Surgeon. Also Assistant House Physician. Each for six months. Salaries at rate of £75 per annum, with board, washing, and apartments.

CARLISLE, CUMBERLAND AND WESTMORLAND ASYLUM, Garlands.—Senior Assistant Medical Officer. Salary £150 per annum, rising to £180, with board, lodging, and washing.

DARLINGTON HOSPITAL AND DISPENSARY.—House Surgeon, unmarried. Salary £120, with board and lodging.

EVELINA HOSPITAL FOR SICK CHILDREN, Southwark.—House Physician and House Surgeon. Salary £60 respectively, with board, residence, and washing. Also Assistant House Surgeon. Salary £70.

GREAT [illegible] Salary £90 per annum [illegible]

GORDON [illegible] bridge-road, S.W.—House Surgeon. Honorarium £10 10s. for six months or £40 for twelve months, with board and residence.

GOSFORTH CITY ASYLUM, Newcastle-upon-Tyne.—Assistant Medical Officer, unmarried. Salary £140 a year, rising to £160, with apartments, board, and laundry.

HOSPITAL FOR SICK CHILDREN, Great Ormond-street, W.C.—House Surgeon, unmarried, for six months. Salary £20, with board and residence.

HOSPITAL FOR WOMEN, Soho-square, London, W.—House Physician for six months. Salary £30.

KIRKMAHOE PARISH COUNCIL, Dumfriesshire, N.B.—Resident Medical Officer and Vaccinator. Salary £30 per annum.

[illegible] —Assistant House Surgeon for [illegible] board and lodging.

[illegible] HOSPITAL.—Resident Surgeon [illegible] m for first six months and £120 per annum for second six months, with board and residence.

MIDDLESEX HOSPITAL, W.—Second Assistant in the Clinical and Bacteriological Laboratories. Salary £100 per annum.

NEWCASTLE-UPON-TYNE, UNIVERSITY OF DURHAM COLLEGE OF MEDICINE.—Demonstrator of Anatomy. Salary from £120 to £150.

NOTTINGHAM CHILDREN'S HOSPITAL.—House Surgeon, unmarried, for six months. Salary at rate of £100 per annum, with board and residence.

NOTTINGHAM GENERAL HOSPITAL.—Assistant House Surgeon. Salary [illegible]

PA[illegible] se Phy[illegible] ate of 50 [illegible]

RO[illegible] Salary [illegible]

[illegible] s Inn road, W.C.—Resident House [illegible] House Surgeon (female), Assistant [illegible] Surgeon (male), Casualty House [illegible] provided [illegible] House Surgeon [illegible] washing [illegible] Also Assistant [illegible]

SAMARITAN FREE HOSPITAL FOR WOMEN, Marylebone-road, N.W.—Clinical Assistants.

SMYRNA MISSION AND HOSPITAL (CHURCH OF SCOTLAND JEWISH MISSION).—Medical Missionary. Salary £250, with dwelling house.

STAFFORD, COTON HILL LUNATIC HOSPITAL.—Assistant Medical Officer. Salary £125 per annum, with increase, board, lodging, and washing.

SUSSEX COUNTY HOSPITAL, Brighton.—House Surgeon, unmarried. Salary £140 per annum, with board and residence.

TAUNTON AND SOMERSET HOSPITAL, Taunton.—Resident Assistant [illegible] Salary at rate of £50 per annum, [illegible]

TOR[illegible] Surgeon. Salary £100 per [illegible] washing [illegible] ologist and Curator of the [illegible]

[illegible] GENERAL HOSPITAL.—House [illegible] with board, lodging, and washing.

Births, Marriages, and Deaths.

BIRTHS.

EYRE.—On Sept. 30th, at Wandle House, Wandsworth Common, to Dr. and Mrs. Eyre, a son.

HIL[illegible] P. T [illegible]

MA[illegible] John [illegible]

PO[illegible] the [illegible]

PIM[illegible] Pim, [illegible]

MARRIAGES.

DAY—GORDON.—On Oct. 3rd, at St. Luke's, Nightingale-lane, S.W., James John Day, M.R.C.S. Eng., L.R.C.P. Lond., D.P.H., of Preston House [illegible] Grace, second daughter [illegible]

[illegible] Catherine's, Old Colwyn, [illegible] M.R.C.S., L.R.C.P., to [illegible] e John Kellett and of Mrs. Kellett.

LANGMORE—JENKINS.—On Sept. 30th, at St. Luke's Church, Tideford, Cornwall, by the father of the bride, Herbert Richard Langmore, M.B., B.C. Cantab., to Sonia, elder daughter of the Rev. D. Jenkins.

DEATH.

DUBIG.—On Sept. 30th, 1903, at Little Langtons, Hornchurch, Essex, John, the son of David John Dubig, aged four months.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

SIX YEARS OF MEDICAL JOURNALISM—A RETROSPECT.

THE October number of the *Scottish Medical and Surgical Journal* contains a lengthy and amusing article under the above heading written by an American, Dr. James C. Johnston, recently editor of the *Journal of Cutaneous and Genito-Urinary Diseases*. In this lifting of a corner of the journalistic veil it therefore happens that the phraseology and some of the allusions give evidence of their Transatlantic origin. Several of Dr. Johnston's paragraphs we can only mention, as considerations of space forbid quotation. Among these are criticisms on over-production in medical journalism, on anonymous correspondence, on reports of societies, and on the "publisher's department." This last is an unfortunate feature of some American medical journals and consists of puffing notices of pharmaceutical products. This portion has usually, if not always, a separate pagination from the rest of the journal so that there should be little risk of the paragraphs being taken for editorial opinions, but as far as possible editorial style or the style of original communications from medical authors is imitated. Dr. Johnston also gives a pathetic description of editorial troubles caused by the shortcomings of authors, such as verbosity, incorrect quotations, incorrect references, and unwillingness to conform to special usages of phraseology, spelling, and so forth. Let us now hear the editor himself, with the reservation that sentences are omitted here and there and with the reminder to our readers that our own experiences, though they tally in some respects, differ in others.

Original articles.—Two motives, in the main, lead a man to present his views to the public. They are that he wishes to add a mite to the sum total of knowledge, or that he wishes to gain a reputation, vulgarly speaking, to advertise himself in the only way legitimately open to him. Both are entirely worthy, but both are subject to perversion. In the first case he may not be able to judge of the value of his own work, he may be so young that enthusiasm betrays him into error (this type of youth has been known to last for 50 years), or his experience may not be sufficient to justify a hearing at all. Few workers' activities are perennial like Virchow's and it is not too much to say that medical men do their best work before 50. This is the point at which the editor should appear as counsellor and friend and advise a postponement or a touch here, an amplification, verification, or condensation there. His efforts are often taken amiss and the manuscript is withdrawn by the indignant author for publication elsewhere. My experience is that nothing occasions an author more annoyance than the return of his article, but when the thing is hopeless, it must be done. Let me say that the editor gathers no great pleasure from the proceeding, in fact, it is the most difficult thing he does. A nice editorial discrimination is required in the case of a man who writes for reputation. If he has something worth hearing, by all means let him have his opportunity no matter what his reputation for advertising. If he dashes madly into print with the result of a Bottini operation before the knife is cold, or because he has found a few cell inclusions, and thinks they prove parasitism as the cause of cancer, plead with him as a brother. If he will not listen, pass him on to another editor. His feelings cannot be hurt. His next dash will be wilder, if possible. Killing is altogether too good for the man whose object is to puff a proprietary preparation under the guise of a contribution to science or who sends his article to all the journals he knows of at once and prays for an immediate hearing. Fortunately the game can never be played but once even when the culprit is a genius like the one who recently secured admission to 20 journals. It is possible for an editor to joke about these things when his race is run, not before.

Perhaps the worst of the lot is the thief (no need to mince matters) who steals another's work, his cases, his methods, even his photographs. The editor knows nothing of the matter until he hears from the victim, of course the harm is done, for the article is printed. He makes what amends he can, knowing himself innocent, but the wrong seems without redress. No one pays any attention to the owner's claims after the fact. They are laid to jealousy and dismissed. Sub-varieties of this genus are those [illegible] works [illegible] els [illegible] ke [illegible] the first and may be dealt with gently and firmly.

A word as to titles. Let the author remember the unfortunate whose evil state forces him to make the volume's index and, remembering, not make his title a synopsis of his communication. It is enough to tell a reader whether the subject attracts him. If one or two words will do so much the better, but it is entirely possible for the caption to be misleading when the error is on the side of brevity.

Book Reviews.—There is one desideratum in a book review, and that is to tell the truth about the book. When it comes to the editor's desk he does *one of two things* with it—he reviews it.

himself if he has time, or he sends it to someone he thinks fitted for the task. If he selects the latter course he does so in fear and trepidation. Time goes on and no review materialises. After a few months the publishers politely request to know if there is any likelihood of a notice ever appearing. After several notes, interviews and telephone conversations, the review is sent. It is evidently written from the preface, is perfunctory, and winds up with: "This work deserves a place in every library." It goes in and the editor hates himself.

Occasionally he gets a surprise and the reviewer makes his comments in fine style. The author is never pleased, but that is beside the issue. The best reviewer is one who not only knows the subject but has written on it, if possible, a book. His justice is then tempered with mercy and he writes with authority as well as infinite sympathy. What he says may go a long way if he signs the review, a good practice in most instances. The average critic thinks his work done when he has picked all the flaws he can find. If there are mistakes, misprints or omissions, by all means let them be pointed out, because these points are helps in preparing a new edition, but it is not possible that any work on medicine is wholly composed of error. Destructive criticism is about the easiest of literary pyrotechnics, and, while it may be a choice spectacle, there is nothing left but acrid smoke. Indiscriminate praise is no better. When the work is a monograph on one topic a good plan, instead of reviewing it in the ordinary sense, is to give the gist of its contents with a comment or two.

Abstracts.—I served my time, five years, in the making of abstracts, and there is nothing, except the index, for which I have greater loathing. Someone must do it. The question is, Who? We must abstract from Russian, Polish, and Scandinavian tongues if we can; must be able to winnow wheat from chaff, make it readable, and compress the work of ten years into not more than 500 words. It is not too much to say that every abstract, properly done, represents from two to three hours' time. Count up the years contained in the single issue of the *Philadelphia Medical Journal* of Dec. 13th. If an article is worthless it can be dismissed in two lines but the mind that weighs it should be judicial. The polyglot genius with medical training who can weigh evidence and sum it up does exist. There are several of him in my ken, but so far as my experience goes he works when he lists, sometimes for glory, sometimes for the love of it, and sometimes for money or the journals. Whatever the motive the reader is his debtor but his word should not be taken as gospel. Quite as useful as the man who pursues original lines of investigation is he who presents an able critical summary of the results of that work. Small thanks he ever gets for it.

I have not touched upon the department of news, for presenting that is a function of the medical newspaper and not of the special journal. The same I hold to be true of editorial writing. It may not be entirely well to tell professional secrets, but there are many difficulties in the making of a magazine which its subscribers seem not to appreciate. I shall have accomplished my object if there comes that better understanding between them and the gentlemen in editorial chairs of which I have spoken.

We have read Dr. Johnston's editorial experiences with interest.

THE DISAPPEARANCE OF MISS HICKMAN.

We have been asked by Mr. Hickman to state that he does not believe his daughter to be confined in a house of ill-fame but rather in some institution like a convent. With regard to the suggestion of opening a subscription among medical men with a view to increasing the reward offered for the discovery of Miss Hickman we have received from a correspondent writing above the initials "A. E. W." the following letter:—

"There must be many who, like myself, would welcome the opportunity to subscribe towards such an object. A far larger reward than at present offered might result in most important information, and especially would this be likely if the informant was assured of free pardon on giving 'King's evidence.' Apart from humane considerations we must remember that if efforts are relaxed to solve the mystery of a suspected heinous crime it is a victory for the criminal classes and consequently a menace to society at large. In this case it would especially constitute a menace to the safety of the medical profession."

Our correspondent offers to send a subscription of one guinea and to double his contribution when £100 have been promised.

SWEDISH EXERCISES.

To the Editors of The Lancet.

Sirs,—I shall be much obliged if one of your correspondents would kindly favour me with the address of the institution where a course of Swedish exercises and gymnastics can be carried out.

I am, Sirs, yours faithfully,

Oct. 6th, 1903. X. Y. Z.

PRECOCIOUS MISCHIEF.

A correspondent writes: "I have been attending a little boy who is a veritable demon for mischief of every description. He is only two years and seven months old but stronger and more intelligent than children usually are at that age. Recently he dismembered a harmonium in order to convert the keys into playing-bricks, utterly ruining the instrument. His last exploit was to strip his baby sister naked and to daub her all over with green paint from a pot which had been incautiously left within his reach. 'When I came in and saw the poor child,' said the mother, 'I sat down and cried.' She scrubbed the paint off the infant with soap and water. The infant must have suffered great agony for most of her epidermis had accompanied the paint. The bodily temperature of both the children is peculiar. In health it does not exceed 97° F. When the boy had pneumonia it rose to what we are accustomed to call normal. The pulse in both infants is unusually slow. Can there be any connexion between his low temperature and the boy's mischievous disposition? The little girl has not as yet shown herself to be abnormally destructive. The parents, a young couple, are in no way out of the common."

MOTOR-CARS FOR MEDICAL MEN.

To the Editors of The Lancet.

Sirs,—I shall be glad if some of your correspondents would give me the benefit of their experience in the use of the motor-car for working a country practice. What make of car is most suitable at a moderate price? Are motors reliable for medical work? And is the expense heavy connected with running them? The roads in my district are fairly good in the summer but decidedly heavy and somewhat rough in the winter months, with few hills.—I am, Sirs, yours faithfully,

Oct. 5th, 1903. General Practitioner.

⁂ The subject of motor-cars for medical men has been much discussed in our columns, but as after all the motor manufacturing trade is in its infancy and constantly undergoing developments it will perhaps be well to invite correspondents to make replies. "General Practitioner" may thus obtain the latest information in answer to his questions.—Ed. L.

THE PUMICE FILTER TOBACCO PIPE.

Since we inserted a description of this pipe in The Lancet of Sept. 19th, p. 860, several correspondents have written to know where it can be obtained. We shall be obliged if the makers will kindly send to us their address.

WANTED—A SCHOOL.

To the Editors of The Lancet.

Sirs,—Can you or any of your readers kindly inform me if there is a school where the daughters of a medical man (who having died and left a widow and two daughters unprovided for) could receive free education or where they would be taken at reduced fees?

I am, Sirs, yours faithfully,

Oct. 5th, 1903. Lideria

◆

Enquirer.—Our correspondent should apply to the honorary secretary of the Society for the Study of Inebriety, Dr. T. N. Kelynack, 120, Harley-street, London, W., or to the honorary secretary of the British Medical Temperance Association, Dr. J. J. Ridge, Carlton House, Enfield, Middlesex.

Bicycle.—Bicycling, unless carried to an injurious degree, has no bad effect upon the menstrual periods. If indulged in, however, during the period it tends rather to increase the amount of the flow. Any standard work on gynæcology gives details as to the treatment of amenorrhœa.

Ignoramus.—The change of address can be advertised with discretion once or twice, while a circular letter to all patients on the books at the time of removal is in order.

Old Student.—Our correspondent had better communicate with the secretary of the Sanitary Institute, Margaret-street, Regent-street, London, W.

X. Y. Z. (Ipswich) has not inclosed his name and address. In doing so he should also forward the rules of the association.

X. Y. Z. (Castle Cary).—We will endeavour to be of use. We presume that the assistant was unqualified.

Delta.—We should think that the books mentioned would be quite sufficient.

METEOROLOGICAL READINGS.

(Taken daily at 8.30 a.m. by Steward's Instruments.)

The Lancet Office, Oct. 8th, 1903.

NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC (Queen square Bloomsbury)—3 30 P M Dr Collier Methods of Examining Cases

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff It is urgently necessary that attention be given to this notice

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication

We cannot prescribe or recommend practitioners

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub Editor"

Letters relating to the publication, sale and advertising departments of THE LANCET *should be addressed "To the Manager"*

We cannot undertake to return MSS not used

MANAGER'S NOTICES.

TO SUBSCRIBERS

WILL Subscribers please note that *only those subscriptions* which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, W C, are dealt with by them! Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c, should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect

The rates of subscriptions, post free, either from THE LANCET Offices or from Agents, are —

FOR THE UNITED KINGDOM		TO THE COLONIES AND ABROAD	
One Year	£1 12 6	One Year	£1 14 8
Six Months	0 16 3	Six Months	0 17 4
Three Months	0 8 2	Three Months	0 8 8

Subscriptions (which may commence at any time) are payable in advance Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, MR. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W C

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE. It has come to the knowledge of the Manager that in some cases higher rates are being charged, on the plea that the heavy weight of THE LANCET necessitates additional postage above the ordinary rate allowed for in the terms of subscriptions Any demand for increased rates, on this or on any other ground, should be resisted The Proprietors of THE LANCET have for many years paid, and continue to pay, the whole of the heavy cost of postage on overweight foreign issues, and Agents are authorised to collect, and do so collect, from the Proprietors the cost of such extra postage.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied Address—THE MANAGER, THE LANCET OFFICES, 423, STRAND, LONDON, ENGLAND

Communications, Letters, &c., have been received from—

A.—*Association of Medical Men Receiving Resident Patients, Bournemouth. Hon. Secretary of*; Association of Public Vaccinators of England and Wales; A R. H.; Dr. J. M. Atkinson, Hong-Kong; Messrs. Armour and Co., Lond.; Messrs. Arnold and Sons, Lond.; Messrs. Allen and Hanburys, Lond.

Advertisements (to ensure insertion the same week) should be delivered at the Office not later than Wednesday, accompanied by a remittan

Answers are now received at this Office, by special arrangement, to advertisements appearing in THE LANCET.

The Manager cannot hold himself responsible for the return of testimonials, &c., sent to the Office in reply to Advertisements; copies o should be forwarded.

Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manag Mr. CHARLES GOOD, THE LANCET Office, 423, Strand, London, to whom all letters relating to Advertisements or Subscriptions should be addres

THE LANCET can be obtained at all Messrs. W. H. Smith and Son's and other Railway Bookstalls throughout the United Kingdom Adv tisements are also received by them and all other Advertising Agents.

Agent for the Advertisement Department in France—J. ASTIER, 31, Rue Bapts, Asnières, Paris.

ABSTRACT OF

An Address

ON

THE IMPORTANCE OF POST-GRADUATE STUDY.

Delivered at the Opening of the Winter Session of the Post-Graduate College, West London Hospital on Oct 13th, 1903.

By Sir WILLIAM SELBY CHURCH, Bart, K C B, M D Oxon,

PRESIDENT OF THE ROYAL COLLEGE OF PHYSICIANS OF LONDON

[In the introductory portion of his address Sir William Church gave an outline of the evolution and history of the Medical Acts He said that in the year 1834 a committee of the House of Commons, with Mr Henry Warburton as chairman, was appointed to inquire into the laws, the regulations, and the usages relative to medical education and practice in the United Kingdom This committee, however, did not present any report. In 1844 a Bill was brought in by Sir James Graham which was practically the same as that which was passed in 1858 as the Medical Act Sir William Church then continued]

It is almost impossible for us to conceive the state of, I will not say the medical profession, but of medical practice in the country at the time when the select committee took evidence Apparently anyone could call himself surgeon or apothecary and could obtain equal advantages with those who held diplomas from the corporate bodies like the Royal Colleges and had undergone an examination and possessed a certain amount of education One of the questions which most deeply moved the mass of the profession then as now was, Should there be penal laws which gave a monopoly of practice to those who held qualifications and prevented their being interfered with by the unlicensed? In my opinion our fathers acted wisely and I feel sure that in our day our legislature will be equally sensible, to me it appears that it would be a most unwarrantable interference with the personal liberty we all value so highly for the State to say that you shall not receive advice as to your health and well being from any person from whom you think you may obtain benefit We who are conversant with disease and its nature and the pathological conditions on which it depends can hardly place ourselves in the position of the laity, their complete ignorance causes them still to consider disease as something foreign to the body which can be driven out by sufficiently powerful means and they fail to recognise that the majority of the chronic ailments they suffer from are due to changes and degenerations in their own tissues which it is beyond the power of physicians to remove

There is no subject on which the general public is so ignorant and credulous as medicine and this is not to be wondered at when we consider the history of our art and how it arose The earliest medical practitioners of whom we have any knowledge the family of the Asclepiads, claimed to be descended from a god and that something divine was attached to them Although in the brightest times of Greek learning medicine, as we see from the writings of Hippocrates, was singularly free from superstitious observances, yet the part played in the public and domestic life of Greece by oracles, dreams, omens from birds, beasts and the phenomena of nature must have caused divination to play an important part in illness In the later days of Greek learning, when the knowledge of anatomy and therapeutics was at its highest level, in the times of Galen and Aretæus, we know from their writings that methods which we can only regard as superstitions were in use in the treatment of the sick The accounts of miraculous instances of healing in the early days of Christianity and the virtues ascribed to the relics of holy men at a later period still fostered the belief that the art of healing was the gift of God and this belief is by no means yet extinct Healing by suggestion occupied a very prominent although unrecognised position in the practice of mediæval times Even William Harvey appears to have had faith in the therapeutic virtues of the bone of a stag's heart, and touching for the king's evil persisted in this country until the reign of George I Those who are students in folk-lore know how deeply the belief in witchery and sorcery had permeated all classes of men and was fostered by the total absence of what I may call the scientific mind among the learned of the Middle Ages They devoted their mental powers to metaphysical questions and, like the Greek philosophers, entirely neglected experimental investigation into the phenomena of nature

I fear you will think that I have wandered far from my subject I thought that the brief sketch which I have given you of the genesis of the Medical Act and the changes which have taken place in the position and education of our profession would be interesting at the present time when the development of medicine appears almost to necessitate fresh educational methods for the fit preparation of those who intend to make it the study and business of their lives

Of the importance of an acquaintance with the sciences, such as physics and chemistry, as a preparation for the study of medicine we are all agreed, but we are not equally of one [illegible] should be acquired To [illegible] liminary education before students enter on their medical course should necessarily embrace the principles of chemistry and physics A student then would enter on his anatomical and physiological studies prepared by his earlier work to make the best use of his time Biological chemistry, pathology, and bacteriology demand so much time and are so valueless unless a man has a certain amount of practical experience while studying them that the present five years course would not enable any unless they are exceptional men to obtain more than a mere smattering of any of them We must remember that for what may be termed the highest branch of medicine, sanitary science and public health, a post graduate course is now required, only those who hold medical qualifications being admissible to the examinations held by the various licensing bodies for the diploma of public health

By a process of natural development even more than by the artificial and arbitrary regulations made by corporate bodies the medical profession long ago fell into three great classes more or less distinct—physicians, surgeons, and apothecaries, the latter of whom at a subsequent date developed into general practitioners The complexity of medicine is now so great that although these three classes remain fairly well marked, the two first are being subdivided into smaller groups It has, however, been wisely decided by the legislature that no one should be admitted to the Medical Register who has not passed a competent examination in the three subjects of medicine surgery, and midwifery consequently it is not until after we have been admitted to the ranks of the profession that we specialise in any way It is evident that it is impossible for anyone to attain to the highest degree of technical knowledge and skill in all departments Good general practitioners are, as a rule, exceedingly well up in their work I am filled with admiration when I consider how seldom they are found incompetent Think of the responsibility which they have—liable to be called on (especially those practising in the country districts) to treat single handed every sort of emergency, sudden illness, a broken limb, a general smash, an alarming post partum hæmorrhage or a placenta prævia or as medical officer of health to combat a sudden outbreak of epidemic disease Yet competent as most of them are to deal with these emergencies of practice, they would be the first to repudiate the title of specialists In the progress of the evolution of medicine the differentiation of physicians and surgeons naturally took place and all honour must be given to the surgeons who have raised their art from the position of a handicraft subservient to the physicians to that in which it now stands higher possibly in the estimation of the public than medicine

Specialism and specialists are terms which are very much misused nowadays The true specialist, whether he be physician or surgeon is one who with a wide knowledge of all has paid especial attention to some particular branch or branches of medicine, such as sanitation or public health, mental diseases gynæcology, ophthalmology, &c, not as the public appear to think the man who has fixed his attention on a single organ of the body In surgery, where to a greater extent than in medicine manual dexterity is required, surgeons in large centres of population are able to make particular study of certain classes of operations in which by constant practice and most careful attention to details they are enabled to improve the methods and to obtain greater success. It is the success of these honoured and honourable men which has led the public to their demand for specialists—a demand which meets a ready response, although I fear the quality of the article supplied is very inferior to that which the public think they are obtaining. A certain number of these so-called specialists are no doubt honest and honourable men, but by directing their thoughts exclusively to a limited range of subjects have lost all sense of proportion, and I fear that no inconsiderable number trade rather on the ignorance of the public than on any superior knowledge of their own. Of all quacks the worst are those who are duly qualified to practise, for by their position as medical men they bring discredit on the profession. All of us who have reached a certain age have seen how these quacks vary with the fashion of the day; at one time all ills the flesh is heir to arise from acidity or gout and in the other sex from versions, malpositions, and ulcerations of an internal organ; at another time adenoids or supposed phimosis is at the root of all disorders of childhood, and at another exploratory operations on the abdomen are the panacea for all internal derangements. Mankind is alike everywhere and in all classes; its credulity does not grow less with advancing times; if we have lost our belief in miracles and relics we need only look at the advertisement pages of any newspaper to see that our credulity has only taken another form.

The time which can now be allotted in the five years course is too short to enable the average man to spend sufficient time in clinical and practical work. It is essential for the student not only to have general experience in the wards but to have attended the special departments and if possible to have held the post of clerk or dresser in them. Those who are fortunate enough to obtain posts in our large hospitals, especially those with medical schools attached, are virtually enjoying post-graduate study of the best kind, but it is a minority of men who can obtain the advantages of holding such posts. This country, as in other educational questions, has, I am afraid, been behindhand in organising post-graduate teaching of any sort. In the United States of America a large proportion of those attending the arts course at the Johns Hopkins University are post graduates and I am informed that at Baltimore nearly one-third of the medical students are qualified men. The first attempt at organising anything of the nature of medical post-graduate study in London was as long ago as 1888 or 1889; a notice used to appear in the medical papers annually above the signature of Dr. J. Fletcher Little, but it was not until about ten years ago that the West London Hospital course was started. The earlier attempts appear to have failed mainly because they took the form of lectures and did not embrace hospital practice. It is in this respect that the West London school is able to offer so much more valuable assistance to qualified men than such institutions as the Polyclinic or the other hospitals at which occasional lectures or demonstrations are given. You have gradually built up a complete medical school and by confining yourselves to qualified men have not interfered with, or given cause for jealousy to, any of the existing medical schools. The practice in the hospitals attached to the great medical schools in London is open to qualified men but it is not possible to meet their requirements. The teaching for the junior students is necessarily different from that most suitable for those further advanced. Any considerable number of senior men attending the clinical practice of our medical schools has always, and rightly, been resented by the junior students.

That there is abundance of room for post-graduate teaching no one can deny; it is, in truth, urgently needed. After qualification a man makes up his mind in what department he prefers to do special work. If he intends to enter on general practice he knows in what subjects he is weakest and can obtain with you the opportunity and assistance for strengthening his knowledge and supplying his deficiencies, for there is no way by which this can be attained equal to closely following the practice of a large general hospital. There are many subjects now which it is essential for a man to know something of, particularly those which are not suitable for him to spend much time over as a junior student. As instances I might mention the application of electricity for the diagnosis and treatment of diseases or injury, the manipulation necessary for the examination of gynæcological, orthopædic, or ophthalmic cases. If opportunities for increasing their stock of knowledge are advantageous to those just entering on their professional life they are no less so to those who have been placed in circumstances which rendered it difficult either to gain new knowledge or to keep up that which they possessed. Especially useful is it to those who have joined our public services; from the nature of their work it is impossible for them in ordinary circumstances to gain varied experience for want of opportunity. In times of peace the work of the officers of the Royal Army Medical Corps is necessarily without much variety. Even if attached to a large home hospital the field for observation is much more limited than that presented in large civilian ones and excepting during war time the larger operations in surgery very rarely come under their notice. Nothing struck me more forcibly when visiting the hospitals in South Africa than that in many instances the older and higher in the service the officer was the more of a soldier and the less of a medical man he appeared to be. This doubtless arises from the large amount of official non-medical work that they have to get through. A principal medical officer's duties are so largely executive that some of them scarcely did any true medical work themselves. This disability which many of the officers of the Royal Army Medical Corps felt and complained of is now, I trust, remedied, as the Advisory Board has recommended that study-leave should be periodically granted to all officers to enable them to attend civilian practice at intervals during their career. By doing this we are adopting a course which has been in practice in other countries. In the naval service the position is much the same. Commissioned to a ship the complement of which consists of healthy men in the prime of life the medical officer's opportunities for gaining experience are limited. It has been my lot as one of the assessors of the Gilbert Blane medals to read the logs of a considerable number of naval medical officers, and excepting when they have been on active war service there is a great monotony in their medical reports. No doubt they, and the officers of the Royal Army Medical Corps when on foreign service, have opportunities of studying certain forms of tropical disease, but here again the similarity of cases is such that the temptation to fall into a rule-of-thumb treatment of them is hard to resist; nevertheless, I should not be doing justice to a distinguished branch of our profession if I did not bear witness to the excellence of some of its work. Naval officers, I am informed, have not been slow to avail themselves of the opportunities which you offer them and I feel sure that those of the sister service will do the same when it is known how much they can learn here.

In case there should be anyone present who may think that in the remarks I have made I have only had present to my mind the advantage of our profession and not given due attention to the purposes for which this hospital was founded and for which it is supported—the relief of sickness and suffering in its neighbourhood—I should like to say that there can be no greater benefit conferred on the patients who receive relief at an hospital than the attachment to it of a school of clinical medicine. Teachers must always be learners and there is no incentive to a teacher so great as the presence of students anxious to learn. You can have no greater safeguard against mismanagement or against slackness and inattention on the part of the staff than the presence of students. They form a body of critics, kindly it may be, but severe and uncompromising, ready to expose the shortcomings and failures of their teachers. I can unhesitatingly say that the character and quality of the medical treatment in hospitals with medical schools attached to them compare favourably in every way with those in which the work is done without the publicity which necessarily exists when clinical teaching is carried out in the wards and out-patient departments. You have an excellent staff, earnest in their work and anxious to maintain and to increase the reputation of your hospital. You have the material and a certain amount of means for carrying out educational work. I trust that in the near future it may be possible for the lay authorities to give increased facilities for teaching and research, and I would venture to remind the supporters of this institution that whilst a few more beds or an increased number of out-patients might relieve a certain small amount of local sickness and suffering that would hold but a small proportion to the benefit which increased knowledge obtained within these walls might confer on suffering humanity throughout the world. In conclusion, I wish all prosperity to the West London Hospital and its Post-Graduate School.

An Address

ON

CHARLES WHITE, F.R.S.: A GREAT PROVINCIAL SURGEON AND OBSTETRICIAN OF THE EIGHTEENTH CENTURY.

Delivered before the Medical Society of Manchester on Oct. 7th, 1903,

BY CHARLES J. CULLINGWORTH,
M.D. DURH., F.R.C.P. LOND.,
OBSTETRIC PHYSICIAN TO ST. THOMAS'S HOSPITAL.

[IN his introductory remarks Dr. Cullingworth referred to his former period of residence in Manchester and to his having held the offices of honorary librarian and afterwards of honorary secretary of the society for a continuous period of 13 years. He then said :]

For many years I have had it on my mind to gather together such materials as are obtainable for a somewhat fuller account than has yet appeared of the life and work of one of the greatest, if not the greatest, amongst the medical worthies of Manchester, Charles White, the friend of John Hunter, the principal founder of your famous infirmary, the founder also, along with the two Halls (Edward and Richard), of the Lying-in Charity, now St. Mary's Hospital, a pioneer in conservative joint surgery, and, above all, the emancipator of the lying-in woman from the deadly dangers to which she had been condemned by the accumulated traditions of centuries of ignorance and superstition. Other writers have to a certain extent forestalled me. In Mr. W. Whitehead's presidential address before the meeting of the British Medical Association held here last year, and also in the address delivered by Dr. D. Lloyd Roberts as President of the Section of Obstetrics and Gynæcology at that meeting, some account was given of Charles White and of his work as viewed from the respective standpoints of the two speakers. Dr. E. M. Brockbank has also got together a very considerable amount of information about Charles White in connexion with the valuable series of biographical sketches of the older physicians and surgeons to the Manchester Infirmary which he is contributing to the pages of the *Medical Chronicle*, and although I desired him by no means to disturb on my account the order of publication of his series of biographies he generously insisted on withholding his sketch of White until after this address had been delivered.

It has been erroneously stated that Charles White was born in Warrington. He was in reality *born in Manchester* of parents who resided there; he was educated there, practised his profession there, and died at only a short distance away—namely, at Sale in Cheshire. His father was Dr. Thomas White, who was born on April 9th, 1696, and who, after practising his profession in King street in a house in which his son succeeded him, retired to his country cottage at Sale and died there on July 20th, 1776, at the age of 80 years. The house in King-street just mentioned was situated on high ground at the corner of Cross-street, on the site afterwards occupied by the town hall, now the home of the free reference library. Contemporary drawings show the house to have had in front of it a terrace approached from the street at each end by a flight of steps and to have been quite the most handsome and conspicuous house in the street.

From the fly-leaf of an old "breeches" Bible, "imprinted at London by Christopher Barker, printer to the Queen's Majesty, 1578," and discovered about 20 years ago in the collection of a secondhand bookseller, it appears that the book came into the possession of the White family about 1728, the year of Charles White's birth, and was thereupon made the repository of the family records. These records commence with an account of Dr. Thomas White's ancestry. His grandfather was "Charles White, Esq., of Benall Abby, near Griersley [Greasley], Nottinghamshire," who was member of Parliament for the county of Nottingham and "Colonel of a regiment under the King in the grand rebellion when he lost his estate." Colonel White had a son Thomas, who was "baptised at Griesley, 28th Dec, 1656," practised as an attorney at Manchester, and died in 1702, when his son Thomas (Charles White's father) was but a child of six. The record goes on to say that Dr. Thomas White and his wife Rosamund had three children—Charles, Sarah, and Elizabeth—born in 1728, 1730, and 1739 respectively.[1]

While still a mere boy Charles was allowed to assist his father in his midwifery practice. After a time he was sent to attend lectures and hospital practice in London and there it was that he formed the acquaintance of John Hunter, which ripened into a lifelong friendship, the two young men going together to the lectures of John Hunter's elder brother, the scarcely less celebrated Dr. William Hunter, then at the height of his reputation as a teacher of anatomy in London. White seems to have begun his studies in London in or about the year 1748, when he was at the age of 20 years. He cannot have been very long in London, for in 1752 he was not only settled in Manchester and agitating for the establishment of a hospital there, but he had also in the meantime supplemented his London experiences by passing a winter at the University of Edinburgh, already becoming famous as a school of medicine. How far his character and future career may have been influenced by his association with John Hunter there is now no means of knowing. I searched in the library of the Royal College of Surgeons of England and elsewhere for any notes, letters, or other records bearing on that association but in vain. On his return to Manchester he joined his father and very soon established a reputation that led not only to a very considerable practice within the town itself but also to an extensive consulting practice in the surrounding district. He was, as Allen's well-known portrait of him indicates, a man of great force of character and immense energy and his powers of physical endurance were quite remarkable. "Even in advanced age," we are told, "he was capable of performing without fatigue very long journeys on horseback and of bearing without injury to his health exposure to the most inclement weather. He required little sleep and was for the greater part of his life an early riser." With these physical qualifications added to mental endowments that raised him far above the majority of his medical contemporaries, it is no wonder that by the time he had been settled 20 years in Manchester he had come to be considered as the head of his profession in the north of England. He remained in almost undisputed possession of this pre-eminence many years, quite up to the close of the century.

[Dr. Cullingworth here quoted extensively from de Quincey's "Autobiography," chiefly in reference to Charles White's medical attendance on Mrs. Schreiber, who had acted as companion and chaperon to Lady Carbery before her marriage to the fourth Baron Carbery, an Irish peer who had a seat at Laxton in Northamptonshire. He then continued :]

It must have been very soon after his return from Edinburgh to rejoin his father in Manchester that the project of a public hospital or infirmary for Manchester *began to be discussed*, for in the *spring of the year 1752*, Mr. Joseph Bancroft, evidently a friend and admirer of the young and enthusiastic surgeon, offered to defray all the expenses of such an institution for one year, provided Charles White, who, let it be remembered, was not yet 24 years of age, would consent to give his professional

assistance The proposal was accepted and a small house was hired in Garden-street, Shudehill, by way of experiment. A few other gentlemen joined Mr. Bancroft, the project was made public, and at a general meeting of the subscribers held in December, 1752, it was unanimously resolved to erect with all convenient speed an infirmary capable of containing 40 beds. Accordingly, on May 20th, 1754, the foundation of the new building was laid, and in April of the following year it was ready for the reception of patients. The story of the Manchester Infirmary has been often told, and never better and more clearly than in the series of papers by Dr. Brockbank, now in course of publication. It is unnecessary, therefore, for me to enlarge upon it here. I need only say that in the first printed list of officers containing the names of three honorary physicians, three honorary surgeons, and two honorary surgeons extraordinary, the list of surgeons is headed by the name of Charles White, and that he remained an active member of the staff for 38 years—namely, until August, 1790, when after an unfortunate and long-continued controversy he, together with five colleagues, resigned his post, the alleged reasons being that the wishes and opinions of the medical faculty had lately been treated with neglect and that alterations of which they gravely disapproved were being made in the constitution of the charity.

On Feb. 18th, 1762, when in his thirty-third year, White was elected and admitted a Fellow of the Royal Society and on the same day he was admitted a member of the corporation of surgeons, now the Royal College of Surgeons of England.

In 1781 the Manchester Literary and Philosophical Society was founded. There resided at that time in and about Manchester a small band of literary and scientific men who had for some years been in the habit of meeting at the house of Dr. Percival and elsewhere and had now decided that the time had come to organise themselves in a more formal manner. The first secretary of the society was the future biographer of Charles White, Thomas Henry, F.R.S., 'Magnesia Henry," as he was called on account of his having discovered a new method of preparing magnesia alba (calcined magnesia). Henry was 78 years of age when his biography of White was written. White was elected one of the earliest vice-presidents and continued to hold office in that capacity for many years. He read several papers before the society, most of which were published in its memoirs. In 1783 he joined in the establishment of a "College of Arts and Sciences," at which instruction was to be given and lectures were to be delivered on those subjects. It is believed to have been the first institution of the kind started in the provinces. White and his second son, Dr. Thomas White, took charge of the anatomical department and delivered, up to 1788,[2] courses of lectures on anatomy which they were enabled to illustrate from the series of anatomical preparations, upwards of 300 in number, that they had gradually collected. It was to this collection, afterwards, in 1808, presented to St. Mary's Hospital and unfortunately for the most part destroyed by a fire which occurred there in February, 1847, that de Quincey refers in one of the later chapters of his "Autobiography."

[Dr. Cullingworth here again quoted from de Quincey chiefly in reference to an embalmed subject in the museum. He also gave an account of the career of a highwayman whose skeleton was in the museum, after which he said :]

Owing in great measure to the advocacy and exertions of Charles White there was founded on May 6th, 1790, a lying-in charity for attendance upon poor married women at their own homes. This event has naturally a peculiar interest for me on account of my long connexion with St. Mary's Hospital, into which the lying-in charity eventually developed. The first medical officers elected included as consulting staff Charles White himself, his son Thomas, and the two Halls, Edward and Richard. They received the uncouth appellation of "men-midwives extraordinary." In 1795 a house was taken near the old bridge, Salford, into which a few in-patients were admitted, and in the year following a large building situated near the New Bailey prison, also in Salford, which had been originally designed for a hotel but had never been licensed, was bought for about two fifths of what it cost the proprietor and converted into a lying-in hospital. But after a few years, chiefly, it is said, owing to want of funds, the number of in-patients gradually diminished, until in 1814 their admission entirely ceased, the charity reverting to its original function of providing attendance at the patients' own homes. It was in connexion with this charity and in the first year of its existence that Dr. Thomas White, the second son of Charles White, delivered the first course of lectures to midwives that had been given in Manchester. He continued to deliver a course annually up to the time of his death in 1793. The lectures in 1794 were delivered by his father. For midwifery was a subject in which Charles White was deeply interested. During the first half of the eighteenth century the practice of midwifery was almost entirely in the hands of extremely ignorant women and it was only in difficult cases that men were called in. White, who for some time after commencing practice had the care of all the parish poor not only of Manchester but of a large district around it, had his attention called very early in his career to the disastrous effects upon the lying-in woman of the mode of management then in vogue and soon determined to do what he could towards bringing about a change. He may in fact be said to have entered forthwith upon a beneficent crusade of which the results soon became manifest and although there is even yet vast room for improvement the women of this country are still reaping the benefit of the revolution he was largely instrumental in effecting. Let us hear his own description of the mode of treatment of the lying-in woman that then prevailed. "When the woman is in labour she is often attended by a number of her friends in a small room with a large fire, which, together with her own pains, throw her into profuse sweats. ...... If the woman's pains be not strong enough her friends are generally pouring into her large quantities of strong liquors mixed with warm water and if her pains be very strong the same kind of remedy is made use of to support her. As soon as she is delivered, if she be a person in affluent circumstances, she is covered up close in bed with additional clothes, the curtains are drawn round the bed and pinned together, every crevice in the windows and door is stopped close, not excepting even the keyhole, the windows are guarded not only with shutters and curtains but even with blankets the more effectually to exclude the fresh air, and the good woman is not suffered to put her arm, or even her nose, out of bed for fear of catching cold. She is constantly supplied out of the spout of a tea-pot with large quantities of warm liquors to keep up perspiration and sweat and her whole diet consists of them. ...... Amongst the poor people who live in cellars and upon clay ground floors the air is still made worse by the dampness and closeness of their houses, and the want of clean linen and cleanliness in general. Those who live in garrets are also in no better a situation, for the putrid miasmata of several families inhabiting the lower part of the house ascend to them. ...... In a few days after delivery the patient is perhaps seized with a shivering fit, and the nurse is surprised, as she protests she has not had the least waft of cold ; more clothes are heaped upon her ; spirituous liquors and hot spices are given her to throw off the cold fit, which most certainly increase the succeeding hot one " Against these barbarities Charles White strenuously set his face. "The evil," says his biographer, Mr. Henry, "was indeed ...... great ...... and the mortality truly alarming. To overcome the influence of prejudice and long-established custom required a manly spirit and steady perseverance united with real professional ability and the possession of the public confidence. With these requisites Mr. White finally accomplished his object. His patients, instead of being confined to their bed for above a week, were permitted to rise on the second day ; the room was well ventilated and kept cool and no cordials or vinous liquors were allowed except when absolutely necessary and under proper restrictions. The good effects of these changes were so evident as to carry conviction wherever they were introduced. The miliary fever almost entirely disappeared and the puerperal soon became of comparatively rare occurrence." I have quoted Mr. Henry's testimony at length, because it is that of a contemporary, and a practising member of the medical profession, as well as being that of a distinguished man of science. After carrying out for 20 years in a full midwifery practice, embracing much consulting work and personal attendance upon women of every rank or condition of life,[3] the enlightened principles just enunciated, White published his celebrated book on the Management of Pregnant and Lying-in Women and so diffused his doctrines throughout the country. The work had an immediate success. One edition followed quickly upon another. Its fame and influence spread beyond the writer's own country. An American edition was published at Worcester, Massachusetts, in 1773, and the book was translated first into French and subsequently into German. "Perhaps, indeed," says Mr. Henry, "few medical books have been productive of more important reform in medical practice, or of more comfort and safety to the subjects for whose benefit it was intended."

---

[2] The opening lecture of the scholastic session in 1786 was delivered on Oct. 8th by Charles White. (Axon's Annals of Manchester, 1886.)

[3] See Preface to White's "Inquiry into the Nature and Causes, &c.," Part II., March, 1801, pp. x. to xii.

I purpose to speak presently of White's published writings in their chronological sequence, but as this, the most important of them, has now been mentioned, it will be convenient to make here any further observations I may have to make about this remarkable book, although in doing so it will be taking it out of its proper order. The author has himself, in an appendix to the second edition (reproduced also in subsequent editions), summarised what he conceives to be the "most material improvements" which his book has been a means of introducing into the management of pregnant and lying-in women. They are: (1) the use of a cold or tepid bath during pregnancy and also during lactation; (2) permitting the shoulders of the child to be expelled by the labour pains only instead of pulling at the child's head the instant it is born, which latter not only prevents the shoulders from making their proper turns, so as to accommodate themselves to the dimensions of the pelvis but also induces flooding and after-pains from retention of the placenta and irregular uterine contractions[4]; (3) allowing the circulation between the child and placenta to cease spontaneously instead of immediately intercepting it by tying the navel string as soon as the child is delivered; and (4) placing the woman in an upright position as early after delivery and as frequently as possible.

The first three of these innovations require no comment, they have long ago been generally accepted and are now regularly inculcated by every obstetric teacher. With regard to the fourth, however, a few words of explanation seem desirable. It was White's strong conviction that freedom from puerperal fever is very closely connected with this question of posture. "Writers," he says, "are still much divided in their opinions of the cause, and even of the nature of the puerperal fever," and "it is obvious," he continues, "that till some greater certainty be obtained with regard to the cause and nature of this disease all attempts towards a rational method of prevention or cure will be vain. There are, however, some particular symptoms attending it which if accurately investigated may greatly assist our inquiries." He then speaks of a rapid pulse as being the most constant and distinguishing symptom and proceeds to draw an inference which shows him to have been a thinker as well as an observer. "Every surgeon," he says, "conversant with [his] business, knows that [this symptom] never fails to attend absorption of matter from abscesses or ulcers, whatever be the other concomitant symptoms. ...... If to these considerations we add that, as the puerperal fever is more fatal in large cities and crowded hospitals than in places where the air is more open and pure, so is the fever occasioned by the absorption of matter ...... [and] that as the puerperal fever does not appear till after delivery, so neither does absorption of matter from an abscess till it be opened and the air have access, we may, I think, with a good degree of certainty conclude that the absorption of matter is the immediate cause of the puerperal fever as well as of that consequent upon abscesses and ulcers." In other words, he recognised, long before Sir James Simpson wrote his classical essay on the subject, the close analogy between the fever that followed surgical operations and the fever to which lying-in women were liable. White was not long before he translated these views into practice and adopted means of preventing and treating puerperal fever founded upon them. "The horizontal position," he says, "to which women are so frequently confined after delivery, greatly favours an absorption of the lochia." "The lochia, stagnating in the womb, and in the folds of the vagina, soon grow acrid, for it is well known that the mildest humours in the human body, if suffered to stagnate, become so, as soon as the air has access to them. These are in part absorbed by the lymphatics." To prevent this absorption he advises that "in a few hours after delivery, as soon as the patient has had a little rest, she should sit up in bed, with a bed-gown thrown over her shoulders. ...... [She] should lie very high with her head and shoulders and should sit up in bed many times in a day, especially when she takes her food and as often as she suckles her child. ...... The sooner she gets out of bed after her delivery the better, even on the same day if possible; she should not defer it beyond the second or third at the furthest." "This frequent upright posture," he says, "is of the utmost consequence and cannot be too much enforced; it prevents the lochia from stagnating, the stools and urine from being too long retained, and promotes the contraction of the uterus, together with that of the abdominal muscles.[5] Notwithstanding his insistence on this matter of posture he by no means neglects other hygienic precautions. The windows are to be opened; there is to be no board or other contrivance to block up the chimney; the curtains are not to be closely drawn; the lying-in chamber is to be in every respect as sweet, as clean, and as free from any disagreeable smell as any other part of the house; the room is to be brushed every day and the carpets are to be taken out to be cleaned and aired; the patient is to be often supplied with clean linen and clean, well-aired sheets are to be laid upon the bed. "For," says he, "cleanliness and free, pure, and, in some cases, cool, air are the greatest necessaries in this situation, and upon the strictest examination it appears evident to me that there never was a miliary eruption without a sweat nor a puerperal fever without either foul air, an accumulation of excrements in the intestines, or confinement of the patient to a horizontal position, ... except in cases where violence had been used ...... or from some very great imprudence." In his treatment of puerperal fever when it has actually occurred he is still guided by the same principles. "Every method recommended ...... as preventive of this disorder should now be enforced in a higher degree in order to its cure." And the chapter concludes with a remarkable paragraph quoted by Dr. Lloyd Roberts in his address last year but well worthy of being repeated. "I must not," he says, "omit to mention in this place the good effects I have experienced from emollient or antiseptic injections into the uterus by means of a large ivory syringe or an elastic vegetable bottle. In those cases when the lochia have become acrid or putrid, and by being absorbed into the circulation have served as a constant *fomes* to the disease, I have by this means known the fever much assuaged and in many cases wholly extinguished; for though, as I have before observed, the quantity of the lochia is not to be much regarded the quality [illegible] matter of infinite importance." White [illegible] tagiousness of puerperal feve[illegible] not been wholly absent from [illegible] declare that out of the large number of lying-in patients whom he had himself delivered he had never lost one nor, to the best of his recollection, had life in one single case been greatly endangered from puerperal fever in any of its forms. No one can, I think, read these extracts (which could easily have been multiplied) without recognising that White's views and practice were far in advance of his time. The whole book, indeed, teems with startlingly modern suggestions and may be read from beginning to end with advantage even to-day.

[4] [illegible] expelled [illegible] witnessed [illegible] on this [illegible] towns- [illegible] expulsive [illegible] tance to [illegible] on given [illegible] aves the [illegible] of con- [illegible] sequence [illegible] sudden [illegible] On In- [illegible] e, 1837). [illegible] y of the child through the os externum as soon as the head was born is now very generally laid aside. There can be no doubt that this imprudent conduct often brought on a retention of the placenta (See White's Treatise on the Management of Pregnant and Lying-in Women. S. Merriman: Difficult Parturition, new edition. London, 1838, p. 152).

[5] [illegible]

The first paper that White communicated to the Royal Society was read on March 27th, 1760, and consisted of an account of a successful operation for ununited fracture.[6] A second paper, also contributed in 1760, described a case of dislocation of the thigh in an adult produced by external violence. His next paper was read before the society in February, 1762, the same month in which his election took place, and gave an account of the value of sponge as a topical application in the arrest of hæmorrhage. He did not lay claim to the merit of being the first to use sponge for this purpose but he was not aware that it had previously been employed to arrest hæmorrhage from the larger arteries. He declared that the inside of fresh and thoroughly dried sponge was, besides being perfectly easy and safe in its application, more certain in its effects than even the ligature itself. This method was largely superseded by the tenaculum invented a few years later by Mr. Bromfeild and White himself soon ceased to apply it except for particular cases. It greatly interested me to hear that Sir Victor Horsley in his brain surgery adopts no other method for the arrest of hæmorrhage than that of sponge pressure and that he also applies it with increasing frequency in his ordinary surgical operations.

White contributed three surgical papers to the "Medical Observations and Inquiries" published by a society of physicians in London. One of these was on a new method of reducing dislocations of the shoulder of long standing, published in Vol. II. (London, 1764) and another, in the same volume, was on a case of tetanus in which the patient's recovery appeared to be the result of immersion in a hot bath. The third paper appeared some years later in Vol. IV. (London, 1772) and described a new method of amputating the leg above the ankle-joint. But shortly before this paper was published there appeared another of much greater importance. It is an account of a case in which the head of the os humeri was removed for caries and the operation is described as being the first of the kind that had been performed, or at least the first that had been made public, though the author admits that there had been instances of the heads of bones being sawn off in compound dislocations. As the question of priority here comes in it may be well to state that Mr. White's operation was performed in 1768 and that the paper was read before the Royal Society on Feb. 9th, 1769. Already, as a matter of fact, there had been placed on record several cases in which the heads of bones had been removed for disease as well as for injury,[7] but we may take it as certain that, so far as White was aware, the proceeding was a new one. His practice was imitated in 1771 by Mr. Bent of Newcastle and in 1778 by Mr. Orred of Chester. With the exception, however, of a case of Mr. Wainman of Skipton-in-Craven, which occurred in 1768 and in which the ends of the bones were excised in a compound dislocation of the elbow,[8] and a case of Mr. Filkin of Northwich in Cheshire, in which the patella and the articular extremities of the femur and tibia were removed in a case of diseased knee,[9] all the cases published up to this time, both in this and other countries, were, so far as I can find, examples of the removal of one articular surface only. The merit of suggesting the more complete operation of excision, in which not only the articular ends of the bones but the whole, or as much as possible, of the capsular ligaments are removed, appears to belong unquestionably to Mr. Henry Park of Liverpool[10] who first published his method in the form of a letter to Mr. Percivall Pott in 1783. It seems desirable to state these facts, inasmuch as it has been claimed for White that he originated the operation of excision of joints for disease. This claim can scarcely be sustained. At the same time he was certainly one of the pioneers in this department of surgery and deserves the credit of having proposed and carried out a conservative method of operating that, so far as *he* knew, was original. The result in his case was successful, for although four inches of the end of the humerus exfoliated the patient could afterwards carry heavy weights and regained all the movements of the arm.

In 1770 he published a volume entitled "Cases in Surgery." This he dedicated to his father and he included in it, along with much new matter, all his previous surgical writings with the exception of the paper on the surgical use of sponge which he had already published in separate form. The appearance of this book is said to have had the effect of widely extending his reputation. It is described on the title-page as Part the First, but there is no record of his having made any further contribution to strictly surgical literature. Of his next book I have already spoken. It was his *magnum opus*, the work upon which his fame most firmly rests and which has secured for Manchester a peculiarly honourable place in the history of obstetrics. Other distinguished Manchester obstetricians succeeded him and worthily maintained the traditions that he had established but none can be said to have been quite his equal or to have in any way dimmed the lustre of his great reputation. Following upon this larger and more comprehensive work came another important contribution to obstetric literature in which he gave the first accurate description published in the English language of the condition known as "white leg."[11] His theory as to the nature and cause of this affection may be briefly summarised as follows. The pregnant uterus, by the violence of its contractions during labour, presses the lymphatic vessels so forcibly against the sharp and often jagged edge of the pubic portion of the pelvic brim as to wound the vessels and cause them to discharge their contents. The lymph thus extravasated usually becomes absorbed sooner or later by the lymphatics in the neighbourhood. In a space of time varying from 24 hours to six weeks the orifices in the ruptured lymphatics close but they do so in such a manner as to constrict, and in some cases to obliterate, the lumen of the vessels, which consequently become gorged with lymph to such an extent as to cause a general swelling of the limb with all the usual signs and symptoms that characterise "white leg." The whiteness is due to incidental compression of the blood-vessels; all the other physical signs, together with the pain, result from the suddenness and extent of the initial distension. The lymph that exudes when the limb is punctured flows not from the meshes of the cellular tissue, like the fluid in anasarca, or from the main trunks of the lymphatic vessels, but from the *minima vasa* of the cutaneous lymphatics. The speedy subsidence of the first violent pain and of the extreme distension is due to the anastomosis of the injured vessels with the vessels more deeply seated, whereby the obstructed lymph is by degrees carried off, though it is many weeks before the relief is complete. This I believe to be a fair though, of course, condensed statement of White's views as to the pathology of the condition he is describing. It is scarcely matter for surprise that such a theory, however ingenious, was not allowed to pass long unchallenged and a supplementary volume was issued the object of which was to reply to the various criticisms that had been offered[12] and at the same time to bring forward a fresh body of evidence in support of the author's opinions In judging of his theory it must be remembered (1) that as all his 14 cases recovered he had no opportunity of examining the condition of the parts by dissection and (2) that we are even yet without a convincing and adequate pathological explanation of this remarkable affection But whatever he thought of its pathology there can be no difference of opinion with regard to the value of White's essay as an original and accurate clinical study, and it is in this light that it will always possess an interest for the historian of obstetric medicine

---

[6] The operation consisted of removal of the ends of the bone and though suggested by Charles White was not actually performed by him but by his colleague Mr. Burchall, who so bitterly resented White's taking the credit of the case that an inquiry was instituted and witnesses were called. A narrative of the proceedings was published by White who therein declared that the only merit he assumed was that of the "invention," not the actual operation, and that he had never stated anything to the contrary.

[7] For particulars and references see note under "Joints, Excision of," in Cooper's Dictionary of Practical Surgery, new edition, by S. A. Lane, vol. ii., London, 1872.

[9] Jaffray's Cases of Excision of Carious Joints, Glasgow, 1806, pp. 52 to 55 (see following footnote).

[10] H Park: An account of the new method of treating diseases of the joints of the knee and elbow, in a letter to Mr. Percivall Pott, Liverpool, 1783. A translation was published in France in 1784 by Professor Lassus. The pamphlet was reprinted with additions by Dr. Jaffray in Glasgow in 1806 under the following title: "Cases of Excision of Carious Joints," by H. Park of Liverpool and P. F. Moreau, de Bar-sur-Ornain, with observations by James Jaffray. Mr. Park's additions to his original letter comprise "a second case as communicated by him in a letter to Dr. Simmons, Nov. 5th, 1789, and published in the eleventh volume of the London Medical Journal" and "subsequent observations" bearing date, Liverpool, Sept. 10th, 1805.

[11] "An Inquiry into the Nature and Cause of that Swelling in One or Both of the Lower Extremities, which Sometimes Happens to Lying-in Women, &c." The first edition was published at Warrington in 1784, the second in London in 1792, and a supplementary volume, Part II., at Manchester in 1801.

[12] The most important of these were contained in (1) an essay published in 1792 by Mr. Trye of Gloucester, surgeon to the infirmary of that place and formerly assistant to Mr. Sheldon, professor of anatomy to the Royal Academy of Arts; (2) an essay in the third volume of Dr. Ferriar's "Medical Histories and Reflections," published in 1798, on an Affection of the Lymphatic Vessels hitherto Misunderstood; and (3) an "Essay on Phlegmatia Dolens," by John Hull, M.D., published in Manchester in the year 1800. It was in this last-named essay that the name "phlegmatia dolens" appears for the first time. Dr. Hull was a botanist with the botanist's instinct to label and to classify everything. He accordingly gave the disease a name in order to be able to fit it into its proper place in the nosology, which he does

His next essay, which appeared in 1790, was entitled "Observations on Gangrenes and Mortifications accompanied with, or occasioned by, Convulsive Spasms"[13] The object of the essay is to call attention to the excellent effects which the author had found to follow the administration in these cases of large and frequently repeated doses of musk and salt of hartshorn The musk was held to be the important ingredient. It is described as possessing antispasmodic, diaphoretic, sedative, and cordial properties It had, so far as the author knew, never been given before for this particular condition nor had it, in his opinion, ever been prescribed in sufficiently large doses He was evidently greatly pleased with himself for having found out a new remedy and prided himself quite as much on the result of this, his solitary excursion into the domain of therapeutics, as he ever did upon being the discoverer of a new operation or the delineator of a hitherto unrecognised disease This brings to an end the series of White's strictly professional writings[14]

In his later years he interested himself with questions of natural history and read a series of papers before the Manchester Literary and Philosophical Society, embracing such different subjects as the regeneration of animal substances, the natural history of the cow considered as a milk producer for the benefit of man, the thigh bone of a mammoth and some new kinds of timber trees three in number, which he believed likely to prove a valuable acquisition to this country "both in point of profit and as trees for ornament and shade" These trees were the black American birch, the Athenian poplar, and the iron, wainscot, or Turkey oak More important, however, than any of these essays was one on "Gradation" in man and in the animal and vegetable kingdoms which was first read in a series of papers before the Manchester Literary and Philosophical Society during the year 1795 and was published in 1799 in the form of a quarto volume with illustrations The essay was suggested by a demonstration of John Hunter at which White was present and in which a number of skulls was placed upon the table in regular series, first the human skull with its varieties, then the skull of a monkey and so on to that of a dog It occurred to White, as he reflected on the question, that nature would not be likely to employ gradation in the matter of skulls alone, but if she adopted it at all would almost certainly adopt it as a general principle The facts and observations he had been able to collect had led him to the conclusion that there is a general gradation in nature, not only between the different races of men but from man to other animals, from one kind of animal to another, from animals again to vegetables, and through the whole vegetable system The author laments his want of a thorough knowledge of natural history, which indeed, is obvious throughout the essay and gives it what may be described as an air of amateurishness But even when that is said it remains a remarkable and interesting production, considering the time at which it was written and the circumstances in which it was composed This treatise provoked a reply from Samuel Stanhope Smith D D, president of New Jersey College[15]

In the year 1803 White was attacked with an eye affection said to have been at that time epidemic At first only the left eye was involved, The pain he suffered in it was extreme and long continued and although the inflammation was eventually subdued the sight of the eye was never completely restored He still continued to practise, however and even to perform operations There is in the library of the Obstetrical Society of London an autograph letter addressed by him to Dr Rigby of Norwich which is interesting not only in itself but as showing the firmness of his handwriting and the character displayed in it, notwithstanding his age and the impairment of his vision The letter is dated "Sale, Sept 6th, 1811," and reads as follows —

> My dear Sir —Give me leave to return you my best thanks for the fifth edition of your excellent essay on the uterine hæmorrhage and particularly for the honour you have conferred upon me by dedicating it to me I read your first edition as well as the MS with great [illegible] have enriched it [illegible] [illegible]

The little villa spoken of in this letter is the house now known as Sale Priory which had belonged to Charles White's father and had been *his* haven of refuge in his declining years as it was now to be his son's At the end of what was once a picturesque grove of forest trees forming part of the priory grounds are the dilapidated remains of a monument of red sandstone originally about 14 feet in height, erected to the memory of his father by the more eminent son Dr Angus Smith in his "Centenary of Science in Manchester" gives a graphic and touching description of a visit he paid to this monument in April, 1881, in company with Dr Joule, the famous discoverer of the mechanical equivalent of heat The following is a copy of the inscription —

> To the memory of Dr Thomas White who after acquiring [illegible]
>
> [illegible] erected this monument A D 1790

White was not destined to enjoy his rural retirement very long, for he soon became totally blind and died on Feb 20th, 1813, at the ripe age of 84 years

Charles White married on Nov 22nd, 1757, Ann, daughter of John Bradshaw, at one time (1753) High Sheriff for the county of Lancaster They had eight children, four sons and four daughters Thomas, his second son, became physician to the Manchester Infirmary and, as has been already stated, undertook, in association with his father, the charge of the anatomical department in the College of the Arts and Sciences instituted in Manchester in 1783 delivering courses of anatomical lectures there in the years 1787 and 1788 He made considerable additions to his father's museum of anatomical preparations He took part in the founding of the Manchester Lying in Charity and Hospital and delivered lectures on midwifery in connexion [illegible] 1790 [illegible] to the time of his death, [illegible] fall from his horse in [illegible] him his "Observations [illegible] Of the other three sons of Charles White one, Charles, died in infancy The third [illegible] Charles was accidentally drowned, in June, [illegible] elder brother Thomas and other [illegible][16] The fourth, John Bradshaw [illegible] medical profession, lived with [illegible] and became one of the medical officers of the Lying in Hospital His career, however, was soon cut short, for he died in 1797, at the age of 27 years, and was buried in the old church at Ashton upon Mersey A tablet in the north wall of the church erected in memory of Charles White and several members of his family indicates the place of interment both of Charles White himself and of his youngest son.

It may be that now and then White yielded to a temptation to which men of predominant intellect and force of character are specially prone, the temptation to let others see and feel the superiority of which they themselves are conscious. Stories have come down to us which show that he did occasionally in his behaviour towards his professional brethren carry matters with rather a high hand, but certainly nothing could exceed the admiration expressed for his character and work both in Manchester and elsewhere by those who being leaders of the profession to which he belonged were best qualified to judge. It is on record that he possessed a clear and pleasant voice and that he was an impressive and inspiring teacher. His painstaking manner in the investigation of a case and his promptitude and firmness in coming to a decision gave his patients unlimited confidence in him. He was a genial companion ever ready to gather as well as to impart information, and his conversation is said to have abounded with entertaining anecdotes. He was a man of whom Manchester will always feel proud and in taking leave of him to-day we can adopt with very slight modification the graceful words addressed to him towards the close of his life by his old friend Dr. Rigby of Norwich,[17] and, after the lapse of nearly 100 years, can still truthfully say "that time has in no degree lessened the sense of our obligation to him, nor can it diminish the great respect that has ever been entertained for his high character as a surgeon, as an author, and as a man."

THE QUANTITATIVE AND QUALITATIVE RELATIONS OF TOXIN AND ANTITOXIN.

BY E. F. BASHFORD, M.D. EDIN.,
GENERAL SUPERINTENDENT, CANCER RESEARCH FUND; GROCERS' RESEARCH SCHOLAR, ETC.

PART I.—SOME CONCLUSIONS DRAWN FROM THE ABOLITION OF THE FATAL ACTION OF A LETHAL DOSE OF TOXIN BY ANTITOXIN, AND THE ABSENCE OF THIS ABOLITION IF THE HUNDREDFOLD MULTIPLES BE TAKEN.

THE following paper has only an indirect bearing upon the routine methods of testing and standardising diphtheritic and other antitoxic sera. These methods fulfil the requirements of testing and are not, from the practical aspect, subject to the following criticism of the hypotheses which have been advanced in explanation of phenomena met with in the course of following them out.

It is usually stated that the quantity of antitoxic serum necessary to render no longer lethal a fatal dose of diphtheria toxin bouillon neutralises the latter. It is one of the purposes of this note to emphasise the limitations within which this method of stating the neutralisation process is true and to point out the important bearing of these limitations on some hypothetical explanations of the apparent nonfulfilment of what is known as the law of multiples when solutions of toxin and antitoxin react with one another in different volumes. The term "neutralisation" is indiscriminately applied both to the reaction between toxin and antitoxin, and to its consequence—viz., diminution or complete loss of the full toxicity of a quantity of toxin. Although intimately related, the two are distinct phenomena. It is unfortunate that the distinction between them is not more generally made. A chemically neutral mixture of toxin and antitoxin will be a physiologically neutral one. What is usually called physiologically neutral mixture is not necessarily a chemically neutral one; the former takes no account of *molecular quantities*. Much confusion is obviated by keeping these distinctions in mind. It must also be remembered that cells or animals, as indicators of the physiological neutrality of a mixture of toxin and antitoxin, do not permit of the sharp definition attainable in determining chemical neutrality, and also, as with some chemical indicators—e.g., turmeric which only gives evidence of free alkali—the physiological indicators only respond to one of the factors in the reacting mixture—viz., the toxin—if the latter be present in sufficient excess to produce illness. In dealing with toxins and antitoxins we have no direct indications of chemical neutrality.

One of the fundamental assumptions of some very prevalent views on the nature of immunity is that 100 times the quantity of antitoxic serum needful to render non-lethal the fatal dose of toxin should render 100 times the fatal dose innocuous.[1] The requirement is practically never fulfilled and it is customary to point out that its fulfilment can alone be possible if the toxin bouillon contains only a single factor capable of reaction with the antitoxin. Conversely the nonfulfilment of the requirement is held to be an argument in favour of the assumption that more than one factor is able to react with the antitoxin. Because the hundredfold multiple of antitoxic serum is not found to render non-lethal so much as 100 times the fatal dose of toxin bouillon it is stated that there must be contained in the latter other factors than the toxin able to neutralise antitoxin, and this assumption requires the further hypothesis that any factors present cannot be possessed of the characteristic toxic action of the toxin, but they must nevertheless still be possessed of the latter's power to neutralise the specific antitoxin. It is only fair to point out that further reasons are also adduced in support of the view that non-toxic products present in diphtheria toxin bouillon may still be antitoxin-neutralising bodies, and I may add that because guinea-pigs frequently die subacutely with paralytic symptoms after receiving a mixture of diphtheria toxin and antitoxin it has been assumed that this is further evidence of the existence of a relatively non-toxic modification of the toxin. Into the question of the relation of the toxic power of a toxin to its antitoxin-neutralising power I do not now wish to enter.

In the first place I wish to discuss why it is not justifiable to require that the hundredfold multiple of the quantity of antitoxin that is able to render non-lethal a lethal dose of toxin should render 100 such lethal doses innocuous.

1. In experiments performed some time ago in Berlin I found, after preliminary determinations, the dose of a diphtheria toxin bouillon which killed five guinea-pigs each of 250 grammes weight between the fourth and the fifth day to be 0·0075 cubic centimetre (contained in 2·25 cubic centimetres of 1 in 300 dilution). The dose which did not kill any of another similar series till between the fifth and sixth day was 0·006 cubic centimetre (contained in 1·8 cubic centimetres of 1 in 300 dilution). In each case the quantity was made up to four cubic centimetres with 0·86 per cent. of saline solution. The syringe was washed out with saline solution and the washings were also injected. The injections were made over the sternal region. Previous attempts to secure two such series as above had given wider margins of difference between the doses of the two series and also between the intervals at which the fatal issue occurred. When the difference between the doses of the two series specified amounted to one-fifth of the determined lethal dose (0·0075 cubic centimetre) it was possible to obtain two series distinguished from one another by one day's interval in the manifestation of the lethal issue. The attainment of this result was probably exceptional because I have not again been able to obtain two doses one of which always killed on the fourth and the other on the fifth day. The smaller dose was as apt to kill on the fourth as the larger was to kill on the fifth day. The two successful series, however, were sufficient to show that the diminution by one-fifth of its quantity sufficed to prevent the fatal dose from fulfilling the requirement that it should kill within four days. In a further series of experiments it was determined that a quantity somewhere between one-twelfth and one-twentieth of the above lethal dose did not manifest itself in any symptoms—*i.e.*, the animals did not lose weight. I did not attempt to define the largest portion of the lethal dose which could be borne without manifest illness. It was sufficient to have obtained a measurable quantity thus characterised.

2. When a series of mixtures of toxin bouillon and antitoxic serum was made, so that in the same bulk of fluid the determined lethal dose was always contained, together with varying amounts of antitoxic serum, that dose of serum which rendered the lethal dose non-lethal within the time limit of four days was determined. Very little serum sufficed

---

[1] *The fatal dose more particularly referred to is the dose of* diphtheria toxin bouillon which kills a 250 gramme guinea-pig within four days, but on this special case very far-reaching general statements are based.

to postpone death (which was still acute) to the fifth or the sixth day. The quantities effecting this postponement were only fractions of the total amount of antitoxin necessary to prevent a lethal issue within four days and still smaller fractions of the amount necessary to prevent absolutely a fatal termination I do not wish to suppose that these fractions of serum were equivalent to the previously determined diminution by one fifth in the lethal dose of the bouillon; the postponement of the lethal issue may possibly have been effected by the abolition of far smaller fractions of the full toxic power of the lethal dose With a greater proportion of antitoxic serum added and the apparent absence of all symptoms there was probably not less than from one twelfth to one twentieth of the toxin dose "free,"[2] as determined in the section above The amount "free" may here have been considerably above this fraction There was no means by which it could be determined that these last fractions of the full toxic power had been rendered completely innocuous, although by the arbitrary addition of excess of antitoxin this would easily have been effected It is needless to enter into further details of "neutralisation" series, such as are familiar to all pathologists and easily accessible in many papers In the reaction between a toxic bouillon and an antitoxic serum there is, therefore, a phase of which the boundaries cannot be accurately defined If one does not assume that a molecule of the one reacts with a molecule of the other, there is on the one hand, the possibility of the presence in the mixture of a measurable fraction of unneutralised toxicity, and on the other hand, of unneutralised—i e, excessive—antitoxicity Just as in section 1 the line of demarcation is indefinite A series of doubtful doses intervenes *between the certainly lethal and the certainly non lethal* It is pure hypothesis to suppose that toxin and antitoxin can only react in one fixed proportion It is further to be noted that it has become the fashion to estimate all these reactions on the basis of a lethal dose which kills within four days Whereas the four day limitation allows of greater rapidity in arriving at comparative results, it does not give greater but less accuracy in determining certainly lethal from *the certainly non lethal doses* The zone between all the certainly lethal and all the certainly non lethal doses may be a narrower one and have more definite limitations if the absolute minimal lethal dose be determined When one is dealing with the absolute minimal lethal dose and the abolition of the lethal action by means of antitoxin, one has at any rate a definite issue to look for in obtaining comparative results If the period of observation be limited, however, to a period of four days within which the issue must be lethal or non lethal this definiteness is lost[3] No attention is paid to the symptoms of illness, which must vary from *nil* to any degree of seriousness in accordance with the size of the fraction of unneutralised toxicity All degrees of neutralisation extending over the wide zone lying between excessive addition of antitoxin and very limited neutralisation of toxicity are thus classed in the same category as "neutralised" and no attempt is made to secure, nor would it be possible to obtain, the same margin of error in all the observations compared In making the determinations all that is sought for is such an addition of antitoxin that death does not occur at all, or at any rate not within four days, and obviously these results will be obtained by very different quantities of antitoxin This procedure, while eminently serviceable for the practical purposes of standardising antitoxin, is not sufficiently accurate for theoretical purposes The wideness of the limitations of what is regarded as "neutralisation" is, I consider, therefore quite sufficient to account for the 100 antitoxin equivalents corresponding "to 16 and in another extreme instance to 136 lethal guinea pig doses," according as there had been physiologically really "under- or over-neutralisation" respectively of the lethal dose multiplied[4] In experiments of this nature the facts ascertained have reference only to physiological neutralisation and it is not correct to interpret these as having a direct and equal bearing upon chemical neutralisation

3 From what has been said above it is obvious that to render non lethal within four days a dose of toxin bouillon, proved to be lethal within that period, it is necessary to abolish the potency of only a fraction of the total toxicity, to reduce the latter, indeed, to the equivalent of that of a dose fatal in five days as noted in section 1 Similarly, to render non lethal the absolute minimal lethal dose, it is only needful to abolish such a fraction of the full toxicity as shall reduce this latter to the non lethal dose still sufficiently large to cause illness—i e, complete abolition of the whole effect is not required Fraser has emphasised this for snake venom ' While 0 35 cubic centimetre of antivenene per kilogramme is required to prevent death from twice the minimum lethal dose of venom, the minute quantity of the $\frac{1}{1000}$th of a cubic centimetre, or nearly 1000 times less (0 0004 as compared with 0 35) is sufficient to prevent death from a little more than the minimal lethal dose of venom, if this dose be the actual minimum lethal, the rendering inert of *any portion of it, however minute, will prevent the* remainder from causing death Kanthack and Cobbett have also drawn attention to the same phenomenon Cobbett obviated the error involved in taking the simple lethal dose as unity, by taking two lethal doses for the starting point, and then determining the ratios for 2, 11, 101 and 1001 lethal doses I take the liberty of directing special attention to Cobbett's experiments in this connexion, for they seem to have been overl

explained

[4] Transactions of the Jenner Institute of Preventive Medicine 1899, p 6

and 4·5 milligrammes of atropine. The latter of these doses must certainly have exercised an influence in excess of that attained by the former dose, and yet it did not abolish all the effects of the dose of morphine, nor for the matter of that was any dose of atropine able to effect complete abolition of the action of the morphine.

The nature of pharmacological antagonism precluded abolition of the lethal effect by a still larger dose. Pharmacological antagonism is certainly not due to direct interaction of the two active agents in question and I only quote the matter here in support of the general contention that between abolition of lethal action and complete abolition of all action (or in the case of toxin and antitoxin of complete physiological and chemical neutralisation) there is a wide margin. Obviously, therefore, to state that a certain quantity of antitoxic serum neutralises the lethal dose is a careless way of saying that it abolishes the lethal action. To require that the hundredfold multiple of the quantity of an antitoxic serum which renders non-lethal a dose of toxin shall *neutralise* physiologically 100 similar doses is erroneous and it is wrong to apply the data to the problems of chemical neutralisation. If it be found that instead of the action of the 100 doses only that of 60, say, is accounted for, this fact of itself does not justify the adoption of an explanation which calls into existence in the toxin bouillon some non-toxic but antitoxin-neutralising substance—i.e., a body physiologically inert but chemically active. It is only legitimate to require that the hundredfold multiple of the quantity of serum shall account for the action of 100 times the toxic fraction abolished in the case of the simple dose of the toxin bouillon—i.e., provided the larger masses acting and their products are indifferent to the reaction, which in all probability they are not. In making comparisons for theoretical purposes it is not justifiable to assume that a constant quantity of a specific antitoxic serum must neutralise the same multiples of the lethal doses of different toxin bouillons of which the lethal doses are contained in different volumes; for practical purposes this variation in the volumes containing a lethal dose matters little.

4. Some of the points raised in the foregoing in regard to deductions based on what occurs for a simple dose and its multiples may be illustrated by a case in which there can be no question of a non-toxic yet antitoxin-neutralising modication of a toxin, nor of an antitoxin. If corrosive sublimate dissolved in 0·86 per cent saline solution is allowed to act on one cubic centimetre of defibrinated rabbit's blood in a 5 per cent. suspension the erythrocytes will be laked after an interval of from four to six hours at 38° C., as follows:—

Corrosive sublimate, 1 in 10,000,	1 0 c.c.	Complete laking.
,, ,, ,, ,,	0·75 ,, ...	,, ,,
,, ,, ,, ,,	0·50 ,, ...	,, ,,
,, ,, ,, ,,	0·55 ,, ...	,, ,,
,, ,, ,, ,,	0·25 ,, ...	,, ,,
,, ,, ,, ,,	0·15 ,, ...	Not complete.
,, ,, ,, ,,	0·10 ,, ...	Slight.
,, ,, ,, ,,	0 05 ,, ...	*Nil.*

To all the test-tubes saline solution is added to raise the bulk to 2 c.c

The limits of the action vary in different specimens of defibrinated blood, probably on account, not so much of varying susceptibility as of variation in the number of erythrocytes in one cubic centimetre of the suspension due to the different extents to which they are removed during the process of defibrination. It is better to obtain more accurate determinations by using higher dilutions of corrosive sublimate and then to choose a dilution which allows of all the stages being included within a convenient compass.

In the above series 0 25 cubic centimetre is the lowest dose which has effected complete laking. In another series of tubes, under the same conditions of experiment, that quantity of rabbit's serum (or any other serum apparently indifferent to rabbits' erythrocytes) is determined which added simultaneously with 0·25 cubic centimetre of the corrosive sublimate solution abolishes[5] the effect of the latter.

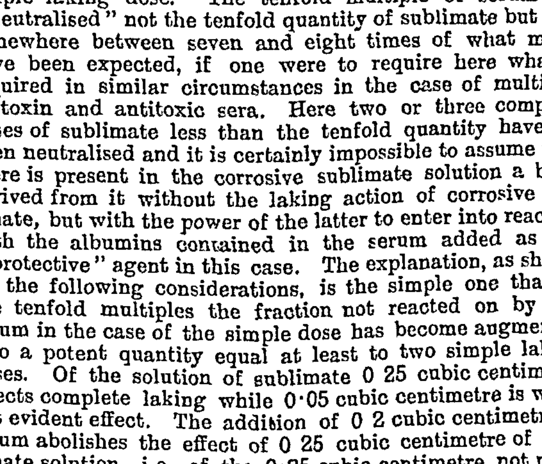
Corrosive sublimate 1 in 10,000.	Serum.	Result.
0·25 c.c.	0.55 c.c.	0
,, ...	0·30 ,, ...	0
,, ...	0·15 ,, ...	0
,, ...	0·20 ,, ...	0
,, ...	0·15 ,, ...	Almost complete laking.
,, ...	0·10 ,, ...	Complete laking.

Here it is only after much experimentation that the results can be obtained in this convenient compactness.

From these two series of experiments we have obtained the information that 0·25 cubic centimetre of the corrosive sublimate solution effects complete laking, that 0 05 cubic centimetre has no effect, that 0·2 cubic centimetre of serum abolishes the effect of 0·25 cubic centimetre of the sublimate solution, and that therefore in the mixture containing 0·25 cubic centimetre of sublimate and 0·2 cubic centimetre of serum there could not have been free to act more than 0·05 cubic centimetre of sublimate solution. If an experiment be now performed with the tenfold quantity of serum we shall see if this quantity be able to abolish the effect of ten times as much corrosive sublimate. The quantity of serum is two cubic centimetres and we add corrosive sublimate in the following quantities:—

Corrosive sublimate (c.c.).	Result.	Corrosive sublimate (c.c.).	Result.
2·50	Complete laking.	1·90	Incomplete.
2·35	,, ,,	1·85	Slight.
2·25	,, ,,	1·80	? trace.
2·20	,, ,,	1·75	0
2·15	,, ,,	1·70	0
2·10	,, ,,	1·65	0
2·05	,, ,,	1·60	0
2·0	,, ,,	1·55	0
1·95	? not complete.		

There is difficulty in determining the exact limit where complete laking and no laking are present. We may take these limits, however, as being with two cubic centimetres and 1·75 cubic centimetres respectively. The difference between these two quantities is 0·25 cubic centimetre—i.e., the simple laking dose. The tenfold multiple of serum has "neutralised" not the tenfold quantity of sublimate but only somewhere between seven and eight times of what might have been expected, if one were to require here what is required in similar circumstances in the case of multiples of toxin and antitoxic sera. Here two or three complete doses of sublimate less than the tenfold quantity have not been neutralised and it is certainly impossible to assume that there is present in the corrosive sublimate solution a body derived from it without the laking action of corrosive sublimate, but with the power of the latter to enter into reaction with the albumins contained in the serum added as the "protective" agent in this case. The explanation, as shown by the following considerations, is the simple one that in the tenfold multiples the fraction not reacted on by the serum in the case of the simple dose has become augmented into a potent quantity equal at least to two simple laking doses. Of the solution of sublimate 0 25 cubic centimetre effects complete laking while 0·05 cubic centimetre is without evident effect. The addition of 0 2 cubic centimetre of serum abolishes the effect of 0 25 cubic centimetre of sublimate solution—i.e , of the 0·25 cubic centimetre not more than 0 05 cubic centimetre is free and not less than 0·2 cubic centimetre has been neutralised. If 0 2 cubic centimetre $= x$ then $0·25 - x = 0\ 05 = 20$ per cent.; if the tenfold multiple be taken then $2\ 5 - 10\,x = 0\ 5$, or two simple laking doses free. With ten multiples of the dose of sublimate the quantity unneutralised has become a multiple of this simple dose—i.e., a dose which was harmless has been multiplied so as to become harmful. It is therefore needless to assume that something else than the corrosive sublimate *per se* has used up the serum added.



Diagrammatic representation of the results of experiments with corrosive sublimate. 1, Minimal dose taken as unity. 2, Largest dose producing no evident action. 3, Shaded on of minimal dose; white area= otent. 4. Result of taking tenfold action abolished; unshaded area= augmented extent of portion not abolished by serum.

---

[5] This is not an antitoxic action on the part of the serum, but ns which in another paper I have because they simulate the toxin-

The erythrocytes are not delicate indicators enough to permit of a "neutralisation" of this nature without the introduction of an experimental error of more than one complete dose in a tenfold multiple. In the "neutralisation" the difference between the tenfold "neutralisation" required and that obtained was nearer three doses than two—the *action only of seven and not of eight simple doses* was completely abolished. This shows that with the hundredfold multiples there would have been a difference of from 20 to 30 doses between the neutralisation point found and that required by assuming complete "neutralisation" of the single dose to have been effected by the quantity of serum which sufficed to abolish its action. I doubt if anyone would venture to suggest that the explanation was to be found in the presence in the sublimate solution of bodies analogous to those nowadays generally believed to be responsible for the similar difference in the case of toxin and antitoxin.

5. Guinea-pigs are not such good indicators of the presence of free diphtheria toxin as rabbits' erythrocytes are of corrosive sublimate. Earlier in this note I have mentioned that one twelfth to one-twentieth of the lethal dose of diphtheria toxin bouillon was certainly borne without any symptoms, but a much larger dose—one-sixth, one-fifth, or even one-fourth—may frequently be followed by little or no sign of illness. In a "neutralisation" experiment, where the presence or the absence of a fatal issue is the criterion of "neutralisation," any lesser reaction would almost certainly be overlooked or regarded merely as transitory œdema, loss of weight, &c., even if prominent enough to attract so much notice. When, on taking the hundredfold quantity of antitoxic serum, it is found that ten, 20, or 30 doses less than the hundred doses of toxin expected are "neutralised," it is not correct to interpret this falling short solely on the hypothesis that in the diphtheria toxin bouillon there is present a derivative of the toxin which is not toxic but yet possessed of antitoxin-neutralising powers. Some proportion of this shortcoming is represented by the difference between the hundredth multiple of the fractions "neutralised" and the 100 complete doses. Another portion will be due to the magnification of the experimental error in the determination of the lethal dose in the same way as an error of more than one whole dose arose in the corrosive sublimate experiments. If these two factors of themselves are not sufficient to account for the whole difference, then, apart from other considerations, it is probable that where bodies of high molecular weight are reacting the process only advances to a certain limit when the products of the reaction cause it to cease. This is, however, a hypothetical consideration.

6 Various observers have drawn attention to the following. When 100 times the quantity of antitoxin required to neutralise the lethal dose reacts with a multiple of the latter the animals experimented on, though they may escape immediate death, frequently suffer from, or even ultimately die with, chronic paralytic symptoms. Naturally the hypothetical non-toxic bodies, which have been held to be responsible for the incapacity of 100 equivalents of antitoxic serum to account for 100 lethal doses of toxin bouillon, have been designated as the cause of this paralysis It will be noted that bodies previously termed non-toxic (they are defined as inert but chemically active) have, to suit this interpretation, to become toxic and paralysis-producing bodies. In determining the absolute minimal lethal dose of diphtheria toxin bouillon the acutely fatal doses are succeeded by others which kill after long intervals up to three or four weeks. Among the guinea-pigs which die after three weeks there are occasionally some which die after the manifestation of paralysis. Some which manifest paralysis recover. I have made no special observations into this matter with toxin bouillon. The above observations have been made incidentally at various times. With a diphtheria toxin precipitated by means of sulphate of ammonium, however, I have been able to confirm the observations of Ransom in regard to the paralysing action of various fractions of the lethal dose of such a toxin. This simply means that doses of *toxin* less than the acutely lethal dose may produce paralysis, may indeed produce paralysis and death subacutely. It does not much matter whether the toxin used was contained in fluid diphtheria toxin bouillon, or in precipitated and dried diphtheria toxin bouillon Some may, however, object that the precipitation of the toxin might modify it and therefore be responsible for the manufacture of a product able to bring about paralysis. Personally I do not entertain the validity of this objection. When these phenomena can be called forth by the toxic body itself, without the addition of antitoxin, I must confess that I do not see any necessity for assuming that the causative agent producing the same phenomena in the cases of doses of toxin imperfectly satisfied by antitoxin is due to a factor other than the toxin present in the bouillon. If the product of the reaction between toxin and antitoxin be able to react with a further addition of either of the latter, it may be that toxin partially chemically neutralised but not saturated with antitoxin gives rise to a product not indifferent to the organism. It would be speculation to ascribe the paralytic phenomena to the activity of this product when toxin alone can produce them. It seems to me that the facts ascertained, however, only justify us in concluding that by means of antitoxin the acutely lethal dose is reduced in its toxicity so that it ceases to be acutely fatal but remains sufficiently toxic to call forth the same paralytic symptoms as the before mentioned fraction of the lethal dose and for the same reasons If not, then one is forced to the assumption that the fraction of the mere lethal dose which calls forth paralysis is able to effect the same degree of injury as can be effected by the sum-total of the difference between 100 and the actual number of doses which are rendered physiologically inert [illegible]

not been enunciated, and it is interesting to observe that Madsen in describing the occurrence of paralysis in guinea-pigs which had received multiple doses of toxin imperfectly neutralised physiologically also accompanies his excellent description of this paralysis in guinea pigs by an equally detailed description of paralytic phenomena noticed in a horse. In the case of the guinea-pigs the paralysis was induced by doses of toxin imperfectly "neutralised" by antitoxin; in the case of the horse, however, it was brought about by repeated injections of sub-lethal doses[7] of toxin alone. The toxin used by Madsen appears to have been toxin bouillon and not precipitated toxin.

It may be asked, Why is it that if sub-lethal doses of toxin alone produce paralysis this phenomena is so rarely seen in determinations of the lethal dose and so often found in experiments directed to determining the physiological neutralisation power of 100 equivalents of antitoxin? The answer is that in the latter case the doses are grouped in a manner which tends to bring into prominence the zone intervening between acutely lethal and non-lethal doses. In the case of the determination of the lethal dose the point to which attention is directed is at the other end of the scale, is the lethal issue, and nowadays a lethal issue within four days. If the zone within which such a pronounced effect as death occurs varies within very considerable limits it is extremely likely that the zone within which an effect manifesting itself after three or four weeks in such very delicate and varying degrees as the diphtheritic paralysis does will vary within wider limits, and guinea-pigs are not ideal animals in which to observe paralytic phenomena. Attention has been directed to the causation of death and the less pronounced manifestations at the other end of the scale of active doses have been very rarely studied.

The considerations contained in the preceding paragraphs show that it is not correct to require that if a certain quantity of antitoxin renders non-lethal a single fatal dose of toxin the hundredfold multiple of this quantity should render physiologically inert 100 similar fatal doses. In taking a large multiple of the fatal dose the fractions remaining potent are multiplied also. They become an agency which has to be reckoned with and may even become a multiple of the toxic power of the fatal dose itself. In cases where their effects become multiples of that of the fatal dose they are largely, if not entirely,

---

toxin

[7] One is forcibly reminded of the relation of peripheral paralysis due to alcohol or arsenic to the acute poisoning by these agents.

responsible for the difference between 100 and the total number of fatal doses accounted for by 100 equivalents of antitoxin. Where they are augmented into sub-lethal effects they may become responsible for the occurrence of paralysis. This line of investigation of itself affords therefore absolutely no evidence of the presence in diphtheria toxin bouillon either of non-toxic modifications of diphtheria toxin which are still able to neutralise antitoxin, or of modifications of diphtheria toxin having the specific power of producing paralytic phenomena.

PART II.—SOME THEORETICAL CONCLUSIONS DRAWN FROM THE PHENOMENA MANIFESTED WHEN MORE TOXIN IS ADDED TO WHAT HAS BEEN DETERMINED TO BE A PHYSIOLOGICALLY NEUTRAL MIXTURE OF TOXIN AND ANTITOXIN.

The physiologically neutral mixture of toxin and antitoxin may be composed of any multiple of the lethal dose and the equivalent quantity of antitoxic serum. It has, however, become customary to take as a basis the hundredfold multiple of the lethal dose or, more correctly, to take what is regarded as being the hundredfold multiple of the quantity of antitoxin necessary to abolish the action of the simple lethal dose The hundredfold multiples have been chosen by distinguished observers for the purpose of instituting a comparison with the phenomena and conclusions drawn from the abolition of the fatal action of a lethal dose of toxin by antitoxin and the absence of this abolition if the hundredfold multiples be taken. No attempt has been made by those who have made this comparison to show that it is a legitimate one. The following considerations will show that it is not. An explanation common to the two sets of phenomena compared in this way has been given on the assumption that they must be due to identical factors. It has been assumed that these phenomena are due to the different affinities for antitoxin of non-toxic or relatively non-toxic modifications of toxin. I have concluded that the line of investigation considered in Part I. gives no evidence of the existence of such bodies. The two phenomena compared are, however, not comparable in this way, for it will be shown that they are not due to identical factors but stand in no direct relation to one another. Some observations which I have made with diphtheria toxin and antitoxin in vivo and with ricin and its antitoxin in vitro have given distinct evidence that either (1) the proportion of antitoxin necessary to effect abolition of the action of a definite quantity of toxin is quantitatively in excess of the portion of toxin actually chemically neutralised, or (2) the product of the reaction between toxin and antitoxin is capable ultimately of modifying the action of higher amounts of toxin than the quantity with which the antitoxin reacts in the first instance.

In illustration of what has just been said the following experiments with ricin and its antitoxin (antiricin) may be given.

Ricin—Abolition of the Action of the Unit Clumping Dose means Interference with the Action of Higher Doses.

(a) *Determination of the unit clumping dose of ricin* (solùtion = 1 in 10,000 of 0·86 per cent. saline solution).

Solution of ricin 1 in 10,000.		5 per cent. blood suspension.		Result after two hours at 38° C.
1·0 c.c.	+	1 c.c.	......	Complete clumping.
0·75 ,,	+	,,	......	,, ,,
0·50 ,,	+	,,	......	,, ,,
0·35 ,,	+	,,	......	Almost, but not complete.
0·25 ,,	+	,,	......	,, ,, ,,
0·15 ,,	+	,,	......	,, ,, ,,

Conclusion.—0 5 cubic centimetre of 1 in 10,000 ricin clumps completely 1 cubic centimetre of the blood suspension.

(b) *Determination of dose of serum necessary to abolish the action of the above dose of ricin.*

Ricin 1 in 10,000		Serum 1 in 20.		Result after two hours at 38° C.
·0·5 c.c.	+	0·20 c.c.	Remained 10 minutes at 38° C., then blood added as above.	Some clumping.
,,	+	0·25 ,,		Trace of ,,
,,	+	0·30 ,,		No ,,
,,	+	0·35 ,,		,, ,,
,,	+	0·40 ,,		,, ,,
,,	+	0·50 ,,		,, ,,

Conclusion.—0 3 cubic centimetre of serum dilution abolishes the action of the unit dose of ricin. In order to obviate the pseudo-antitoxic action of normal serum the serum was diluted 1 in 20.

(c) *Determination of the limits of action of 0·3 cubic centimetre of the serum dilution.*

Ricin 1 in 10,000.		Serum 1 in 10.		Result after two hours at 38° C.
0·50 c.c.	+	0·3 c.c.	Remained 10 minutes at 38° C., then blood added as above.	No clumping.
0 55 ,,	+	,,		Slight clumping.
0 60 ,,	+	,,		Gradually increasing clumping.
0·65 ,,	+	,,		
0·70 ,,	+	,,		
0 75 ,,	+	,,		
0·80 ,,	+	,,		
0·85 ,,	+	,,		
0 90 ,,	+	,,		
1·00 ,,	+	,,		
1·05 ,,	+	,,		Only moderate clumping.
Control ricin.		Serum 1 in 10.		
0·5 c.c.	+	0·3 c.c.		No clumping.

(d) *Confirmation of experiment* (c).—The conditions were the same as in (c) but here quantities of saline solution (0·86 per cent.) were added to each test-tube to raise the bulk to one cubic centimetre before adding the serum; this allows of stating the result in absolute quantities of ricin contained in one cubic centimetre in each tube.

Ricin 1 in 5000.		Serum 1 in 10.		Result after two hours at 38° C.
0·25 c.c.	+	0·3 c.c.	Remained 10 minutes in incubator at 38° C, then blood added as above.	No clumping.
0·30 ,,	+	,,		(?) Slight clumping.
0·35 ,,	+	,,		
0·40 ,,	+	,,		Gradually increasing clumping.
0·45 ,,	+	,,		
0·50 ,,	+	,,		
0·55 ,,	+	,,		
0·60 ,,	+	,,		
0 65 ,,	+	,,		
0 70 ,,	+	,,		
0·75 ,,	+	,,		
0·80 ,,	+	,,		
0 85 ,,	+	,,		
0·90 ,,	+	,,		
1·00 ,,	+	,,		Very strong but not complete clumping.
Control ricin.				
0·25 c.c.	+	Saline + blood		Complete clumping.
0·25 ,,	+	Serum 1 in 10, 0·3 c.c. + blood.		No clumping.

Conclusion from experiments (c) and (d): The quantity of serum which abolishes the action of 0·05 milligramme of ricin also interferes with the action of much higher doses of ricin.

The experiments were performed with the red blood corpuscles of the rabbit after centrifugalising free from serum and suspending them in 0·86 per cent. saline solution. The antitoxic serum was also derived from a rabbit. As is well known, ricin clumps together the red blood corpuscles of the rabbit. In the first instance one determined the smallest dose of ricin able completely to clump one cubic centimetre of the blood suspension after two hours' contact in the incubator at 38° C. Then in another series to it varying quantities of the antitoxic serum were added to this dose of ricin as a constant quantity. After the serum and the ricin had remained in contact for ten minutes in the incubator[8] the blood was added and after two hours in the incubator the degree of clumping was noted. In this way the smallest dose of antitoxin able to abolish the clumping action of a dose of ricin taken as unity was determined. In two other series the quantity of antitoxic serum thus determined remained constant; the quantities of ricin varied. The results showed that the smallest quantity of antitoxin (antiricin) able to effect abolition of the action of the dose of ricin taken as unity was also able to modify the effect of much larger doses of ricin when the experimental conditions were altered. For in the two series with varying doses of ricin abolition of the action of the dose of ricin taken as unity also involved an extension of the abolition much further up the series of doses of ricin. Where one would have expected the unit dose of ricin to be again "free" to act—e.g., at two or three times unity—the action manifested fell much behind that of the unit dose of ricin. From this experiment, which has been confirmed by many repetitions, I draw the conclusion that either (1) one must make the assumption that the proportion of antitoxin necessary to effect abolition of the action of a definite quantity of ricin is quantitatively in excess of the proportion of ricin actually physiologically neutralised, and of this there is no evidence; or (2) that the product of the reaction with the smaller quantity of ricin is capable ultimately of taking up a higher amount of ricin than that quantity with which the antiricin reacts chemically in the first instance and that neither in the case of the smaller nor of the larger doses of ricin within a definite range of doses is there free ricin or free antiricin.

---

[8] This duration was chosen to obviate fallacies arising in precipitation of the constituents of the ricin solution by the antiricin serum.

In the above experiment the toxin was ricin and the experiment was performed in vitro. In the case of diphtheria and tetanus toxins and antitoxins I have met with phenomena of a similar nature and such as have been recorded especially by Knorr and by those who have advanced the views under criticism. When more toxin i added to what has been determined to be a physiologically neutral mixture of toxin and antitoxin it is necessary in order to obtain again the full action of the dose of toxin taken as unity to add, not one unit of toxin, but several; the reasons are possibly identical with those obtaining in the above experiment with ricin. In the case of ricin the full effect of the dose of ricin taken as unity was in the presence of antiricin not obtained again till more than three times this unit was present. In the case of the experiments with diphtheria toxin and antitoxin a physiologically neutral mixture (made on the basis of hundredfold multiples) was not converted into a mixture able to produce again the effect of the dose taken as unity till more than three times the latter quantity of toxin had been added. This was the smallest quantity which caused the full effect to be reproduced and obviously the considerations in the first part of this paper will have made it evident that the quantity required to produce this effect will vary in proportion to the amount of unavoidable error in determining what was a physiologically neutral mixture. It has been demonstrated in Part I. that what is defined as a physiologically neutral mixture is no constant quantity but that by this term a whole series of mixtures (in which at one end there is present a qualitative excess of antitoxin and at the other end just enough antitoxin) are equally well designated and, indeed, are indistinguishable by any methods at our command. These experiments lead to the natural conclusion that a constant volume of a solution of antitoxin reacts in more than one quantitative relation *with volumes of toxin as illustrated* here, especially for ricin.

No further explanation is needed in order to point out the absolute difference and entire independence of the phenomena which are responsible on the one hand for the abolition of the fatal action of a lethal dose of toxin by antitoxin and the absence of this abolition if the hundredfold multiples be taken; and, on the other hand, the necessity for adding more than one unit of toxin to what has been determined to be a physiologically neutral mixture of toxin and antitoxin in order that the full effect of a unit of toxin may be again manifested. It will now be evident that any attempt to explain these distinct phenomena by making them dependent upon the same causative factors must be wrong. In particular the view that the factors in both instances are non-toxic or relatively non toxic modifications of toxin of the same, a greater, or a less affinity for antitoxin than is characteristic of the toxin, is not in accordance with the facts. The assumption that the existence of physiologically inert but chemically active modifications of toxin causes the apparent non-fulfilment of the law of multiples must be given up, although it is hypothetically adequate to account for the phenomenon, and the explanation sought in the unavoidable experimental errors of a qualitative and quantitative nature and in toxin and antitoxin reacting with one another in more than one fixed proportion.

CONCLUSIONS.

In investigating toxin alone it has been shown that—

1. The volume containing the lethal dose can be converted into one no longer lethal within the time limit by diminishing the total volume by a small but measurable fraction of the whole.

2. A measurable quantity of toxin solution can be borne without the production of any symptoms.

Both these effects can be obtained in a different guise when one is dealing with a mixture of toxin and antitoxin, for it has been ascertained that—

3 The poisonous action of the lethal dose may be abolished within the time limit by the addition of a very small quantity of antitoxin; the experiment gives evidence of a qualitative reduction in the toxicity itself, but no evidence of the occurrence of the quantitative reduction referred to in conclusion 1.

4. When the toxic power of a quantity of toxin has been reduced by antitoxin to such an extent that no symptoms appear a measurable degree of toxic power is still potent qualitatively, but we are not entitled to state this in the quantitative terms of conclusion 2.

It has further been found that—

5. The lethal dose is separated from the non-lethal not by a hard-and-fast line but by a zone wherein are contained appreciable fractions of the lethal dose; the data here are quantitative.

6. In mixtures of toxin and antitoxin in such proportions that a lethal issue occurs and does not occur, the margin between the toxic powers of such mixture is not sharp but is a zone, and the actions standing at the upper and lower limits of this zone differ from each other by a measurable fraction of the total toxicity; the data here are purely qualitative.

7. It is not justifiable to assume *a priori* that one volume of antitoxin solution always fully accounts for one volume of toxin solution when mixed in varying multiples. This presupposes that quantitative excess of either is possible and measurable, and ignores the fact that we cannot estimate the quantitative and chemical relations of toxin and antitoxin, but merely the qualitative physiological characters of the mixture, and this only when the toxic power present is manifestly in excess. It is preferable to speak of the retention of active toxicity or of active antitoxicity in characterising such mixtures. The phrases "free toxin" and "free antitoxin" may not be in accordance with the facts and should be abandoned.

8. The above facts indicate the limitations within which it is possible to determine the volume of the lethal dose of toxin and the volume of antitoxic serum sufficient to abolish its lethal action—i.e., the qualitative determination of a physiologically neutral mixture of smallest bulk. If the volumes thus determined be merely multiplied one hundredfold a qualitative indication of the amount of the experimental error present in the original determination is obtained, but no basis for deductions as to the quantitative and chemical relations existing between the toxin and antitoxin contained in the reacting volumes. The assumption that data thus obtained permit of conclusions of a far-reaching nature as to the quantitative relations and intimate chemical nature of the reaction involves a confounding of the abstract with the concrete.

9. The smallest quantity of antiricin which just suffices to abolish the action of a unit dose of ricin, that is the smallest qualitative equivalent of the latter, modifies the action of higher doses of ricin. This shows that the unit dose of ricin is but one of a series of doses to which this quantity of antiricin has a qualitative relation and the fact can only be interpreted as proving that one and the same volume of antiricin has quantitative relations with more than one volume of ricin. At one end of the scale of doses of ricin, with which qualitative relations exist, there will be active if modified antitoxicity, as, e.g., with the *unit dose of ricin*, and at the other end active if modified toxicity, but neither ricin nor antiricin is really "free." The phenomena noted for mixtures of diphtheria toxin and antitoxin and for tetanus toxin and antitoxin are exactly comparable to those obtained with ricin and antiricin and are to be explained by the existence between these toxins and antitoxins of similar quantitative relations in accordance with which they react with one another in more than one fixed proportion.

The results on which this paper is based were obtained previously to November, 1902, and have already been communicated to the scientific assessors of the Worshipful Company of Grocers; other duties have interfered with earlier publication. In a recent number of the *Annales de l'Institut Pasteur* Bordet has announced similar results. Bordet followed different lines of investigation and his results were of a nature to warrant him drawing more definite and far-reaching conclusions than I feel justified in making at present.

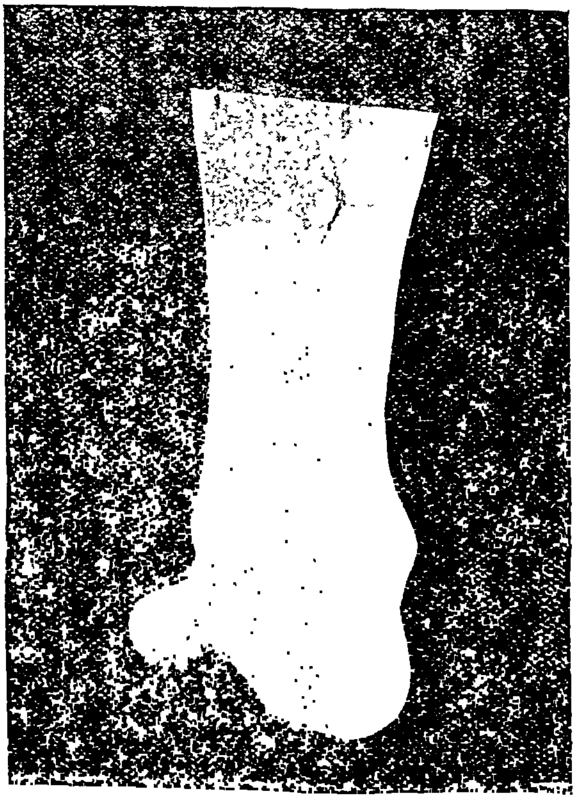
ROYAL DEVON AND EXETER HOSPITAL.—In accordance with ancient custom the committee and governors of [illegible] ayor and corporation anc [illegible] lies will go in pro- ces [illegible] *to Exeter Cathedral* where a sermon will be preached by the Rev. Chancellor Edmonds and a collection will be made on behalf of the funds of the institution.

A CASE OF UPWARD DISLOCATION OF THE FOOT.

By PERCY W. G. SARGENT, M.A., M.B., B.C. CANTAB., F.R.C.S. ENG.,
RESIDENT ASSISTANT SURGEON TO ST. THOMAS'S HOSPITAL, LONDON.

I AM indebted to the late Professor William Anderson for permission to make use of the following case which was admitted to St. Thomas's Hospital under his care in 1899. It appears from the literature of the subject to be an accident of extreme rarity, the salient features of the case being that the astragalus, retaining its normal relations with the foot, was driven upwards between the tibia and fibula without fracture of either bone.

The patient was a short muscular man, aged 46 years, a carman by occupation. He fell from a loft, a distance of about nine feet, and alighted on the soles of the feet upon a heap of stones, falling to the ground immediately and twisting his foot in so doing. There was no history of any previous injury or disease of the joint. On examination, as the patient lay on his back upon the couch with the legs extended, the right foot rested on its outer border, having been rotated at the ankle through a complete right angle. The relations of the tarsal and metatarsal bones to one another were unaltered. The tibia lay in its natural position, the crest and internal malleolus being markedly prominent, whilst the fibula was displaced backwards. The inferior articular surface of the tibia could be distinctly felt beneath the tightly stretched skin which was in no place lacerated. The heel was markedly prominent. The illustration from a plaster cast taken shortly after the accident (see figure) shows the widening between the malleoli, which amounted to over two inches, and the approximation of the malleoli to the plane of the sole. No evidence of fracture could be obtained either by manipulation or by means of the x rays as seen in a skiagram which was taken by the late Dr. Barry Blacker. The foot was firmly fixed in its new position. Under an anæsthetic the dislocation was readily reduced by simple traction on the foot. Massage and passive movements were begun on the third day and the patient was able to walk with only a slight limp at the end of three weeks. He subsequently made a complete recovery.



From a photograph of a plaster cast of the foot taken shortly after the accident.

The dislocation appears the more remarkable when the enormous strength of the ligaments uniting the lower extremities of the tibia and fibula is considered. As described by Mr. Henry Morris[1] these are: (1) inferior interosseous, a dense felted mass of short fibres passing transversely one and a half inches in depth, and extending between (2) the anterior and posterior inferior tibio-fibular ligaments; and (3) the transverse inferior tibio-fibular ligament. Experimentally on the dead subject the dislocation could not be imitated until not only these and the lateral ligaments of the ankle but also the lower part of the interosseous membrane had been divided. In spite of their great strength these ligaments must have been ruptured, since there is no evidence that any portion of either bone was torn away. As the superior articular surface of the astragalus is wider in front than behind extreme dorsal flexion of the foot puts these ligaments upon the stretch and tends to separate the tibia and the fibula. If now the foot is so fixed as to prevent movement at the mid-tarsal joint and then forcibly everted as a whole, the tendency is still farther to separate the two bones and also to bring the outer edge of the upper articular surface of the astragalus against the inferior tibio-fibular ligaments. In this position if force is applied upwards to the foot this edge of the astragalus will form the thin edge of a wedge and thus the whole bone can be forced upwards, separating the tibia from the fibula. In the present instance the foot was rotated outwards through a right angle and the fibula displaced backwards, so that a further movement of supination must have taken place at the superior tibio-fibular joint. There was no evidence of dislocation at that joint or of fracture of the fibula.

I have been able to find only one similar case recorded. This one, of which there is a cast in Guy's Hospital Museum, is described by Bryant.[2] It occurred in both feet simultaneously, in a man, aged 38 years, who fell from a scaffold. The malleoli were widely separated and projected; the depth of the foot from the malleoli to the plane of the sole was lessened and there was no evidence of fracture. The feet were firmly fixed in the abnormal position and reduction being found impossible the patient recovered with stiff joints. Bryant[3] also mentions a case of a similar nature but complicated with fracture of the astragalus. In Treves's "System of Surgery"[4] Mr. A. Marmaduke Sheild describes the accident as being excessively rare and points out that fracture of the malleoli may complicate it. Mr. G. H. Makins[5] remarks that there is some doubt as to whether in such cases the separation of the tibia and fibula is not actually due to an oblique fracture of the tibia; and notes that reduction has proved extremely difficult or impossible. Hamilton[6] speaks of a lateral dislocation of the tibia from the fibula at the lower end, where the fibula may remain unbroken and undisturbed, the tibia having become displaced inwards. He points out the rarity of absence of fracture and notes that the injury is usually compound. Boyer[7] writes: "I have had the opportunity of seeing an incomplete dislocation of the astragalus upwards ('en haut') and inwards in a man who had fallen from a horse," but no mention is made of fracture. This also remained unreduced. Nélaton[8] says: "The upward dislocation necessitates at the same time a fracture of the fibula, and a separation of its inferior extremity from the tibia. The astragalus retains its normal direction but is raised between the two bones." He also points out the increase of the intermalleolar measurement, the proximity of the malleoli to the sole, and the immobility of the foot. Benjamin Anger[9] quotes Nélaton as to the name "luxation en haut" but gives neither description nor instance. He describes a case of "dislocation by rotation," the foot having been turned outwards through a right angle but without separation of the tibia and fibula.

Summary.—The chief points of interest in this case, some of which can be observed in the reproduction of a photograph of the cast, seem to be: (1) the increase of the intermalleolar measurement; (2) the prominence of the heel; (3) the approximation of the malleoli to the plane of the sole; (4) the absence of fracture; (5) that the injury was not compound; and (6) the extreme ease with which reduction was effected.

NOTE ON A CASE OF RENAL CALCULUS.

BY H. E. BRUCE PORTER, M.R.C.S. ENG.,
L.R.C.P. LOND.

THIS note upon a case of suppuration of the right kidney caused by a calculus which first gave rise to symptoms 12 years ago and which for the whole time was mistaken for sciatica may be interesting in the light of recent correspondence in THE LANCET upon sciatica.

The patient, a woman, aged 35 years, sent for me early in 1901. When asked what she complained of she seemed to make light of her trouble, replying, "Oh, it is only a touch of my old friend sciatica." As the patient was to my mind rather young to have old friends of such a nature my next query was, "When did you first have sciatica?" I was informed 12 years ago and that it was so bad that she was in bed for some weeks, her then medical attendant devoting much thought to the case and using every means in his power to cut short the attack. As the treatment had no effect on the disease she was sent to the German baths and spent the best part of three years seeking relief without much success. My next query was, "Please tell me about your present attack." The patient replied that she had lunched out an [illegible] felt rather out of sorts and [illegible] fit which returned off and o [illegible] of a dull character in the right side, there was frequent micturition, and her temperature was 102° F. The right kidney seemed the most probable seat of trouble and it was felt to be enlarged and tender; there was no tenderness over the sciatic region. I now returned to the history of the sciatica of 12 years or so ago. The onset of this was sudden while out walking and, in the patient's words, she walked home doubled up with pain. This did not sound like sciatica. Everyone knows how a patient with this trouble walks—certainly not doubled up. The pain ran down the inside and outside of the thigh and at times was in the sole of the foot. It was not affected by the position of the leg—in fact, as she put it, the pain made her squirm. The first attack lasted, as I have said, off and on for three years and during this time she believed that the urine was examined; she had never noticed blood in it. For the last nine years she had always had an uncomfortable feeling in her right side and occasionally attacks of "sciatica" (?). During these attacks she had noticed the urine to be thick but took no particular notice beyond observing the fact.

The patient was married about four years ago and was pregnant for the first time 12 months later. When three months pregnant the pain in the right side became worse; she also had so much swelling of the hands that she could not wear her rings; she was given to understand that this was due to her pregnancy and her urine was not examined. The pain in the right loin during the later months of pregnancy was worse but was all put down to the uterus. Since the birth of her child she had had to give up many of her pursuits and from being active became the reverse. At times she was unable to bear anything tight around the waist. The lungs were quite healthy and there were no signs of wasting—in fact, considering the history the patient was very well nourished. There was no history of phthisis. I ordered the whole of the urine passed during the next 24 hours to be saved in one vessel, the clear portion to be poured off, and the sediment to be sent to me. This contained one-sixth albumin; a few pus cells were to be recognised und [illegible] r crystals except urates. I [illegible] case was either calculous [illegible] the kidney, that the attack [illegible], and that during pregnancy the change had become more rapid in the breaking down of renal tissue. I advised complete rest and also advised the husband to have a second opinion, pointing out that the urine ought to be examined by a bacteriologist to exclude as far as possible the tuberculous cause.

Dr. Archibald E Garrod made an examination. In the urine of the second 24 hours there was more pus (about three drachms). He agreed with my view of the case and took a specimen of urine to town to have it examined for tubercle. It was found free from tubercle and though the negative result did not exclude the possibility of tuberculous disease it was an additional point as there was no evidence of trouble in the chest, and the history of what we were both agreed was an attack of renal colic 12 years previously made us hope the case would prove to be one of calculous kidney. The temperature varied between 102° F. at night and 100·4° in the morning. On Feb. 25th the patient's child being put on the bed pressed against the damaged kidney, the result being that the swelling was much greater. It could now be seen as an oblong tumour in the right side of the abdomen. On the morning of the 26th, as the pus was not coming away freely enough, hot fomentations were applied. On the 27th the pus was coming away more freely. Sir Frederick Treves came to see the patient to decide when he would advise operation. He confirmed by his examination of the case and history the view taken by Dr. Garrod and myself—i.e., that the trouble began with an attack of renal colic which was then taken for sciatica. He decided that it was a case for removing (when the active stage had passed and the temperature had become normal) what was a serious menace to life. Pus continued to come away and on May 6th the patient's temperature touched the normal line in the morning, rising to 99 4° at night. As it was necessary to have the patient in a surgical home in town for the operation I allowed her up for one hour on the 8th. The temperature went up to 99 6° in the evening. On the 9th the temperature was again normal. The patient was up for three hours. The temperature on going to bed was 101° but came down after she had been in bed about an hour. On the 11th I took the patient to town and she stood the journey well. On the 13th Sir Frederick Treves operated. The organ was removed from the front; an incision was made along the right semilunar line for a considerable extent. The other kidney was examined and found to be quite healthy; the ovaries were also felt and found to be healthy; the right kidney was adherent at the upper end so the lower was delivered first. It is not necessary to describe the various steps of the operation, so I will content myself with saying that the wound was closed without the insertion of a drainage-tube and the patient was taken back to bed. The kidney was a mere shell of pus; there was not a trace of renal tissue left. It contained at least 15 ounces of pus. The calculus which had evidently started the trouble had become quite disintegrated. The patient had a good night and the urine passed was quite healthy. The patient made a good recovery except for the delay caused by the formation of an abscess in connexion with the stump of the ureter. About ten months later the patient became pregnant and this pregnancy was free from the pains, &c., of the former one. The child was born at term. I think the case of interest as showing that in a young woman the symptoms caused by a renal calculus had given rise to the idea that she was suffering from sciatica. The patient is now in perfect health and certainly looks and feels years younger.

THE TREATMENT OF SCIATICA.

BY J. MICHELL CLARKE, M.A., M.D. CANTAB.,
F.R.C.P. LOND.,
PROFESSOR OF PATHOLOGY, UNIVERSITY COLLEGE, BRISTOL; PHYSICIAN TO THE BRISTOL GENERAL HOSPITAL.

MY reason for writing this short paper is that I believe that the Weir-Mitchell method of treatment of sciatica by immobilisation of the affected limb by means of the long splint is not so generally employed as it deserves to be. It is true that there are references to the method in some of the text-books but they are brief, and although Dr. I. Burney Yeo gives a longer and more satisfactory description in the last edition of his "Manual of Medical Treatment," it does not seem to be generally known that obstinate and protracted cases of sciatica can be successfully dealt with in this way. It is not my intention to enter into the discussion of what is the exact nature of sciatica but to confine myself to a brief statement of my experience of this particular mode of treatment in severe cases of this very troublesome complaint.

Although in its mild forms, and when of short standing, sciatica easily yields to constitutional and local treatment of various kinds, in its severer varieties it is one of the most intractable maladies with which we have to do, trying the patience alike of physician and patient. Every now and then a patient, most frequently a male, presents himself suffering from this most painful complaint which has incapacitated him from work for a longer or shorter period and for which he has generally tried many forms of treatment, both regular and irregular. If the patient has to earn his living he generally tries to go on as long as possible in spite of pain or with only partial relief from remedies. I believe it is this neglect in the early stages that makes the disease in certain cases so intractable and difficult of cure. So long as there is any pain the complaint is not cured and is liable to relapse from a mild into a severe form. It was whilst treating a severe and long-continued case in which many measures had been tried without benefit that I first employed Dr. Weir-Mitchell's plan of treatment and this was completely successful. Since then I have carried it out in all severe cases of sciatica that have come under my care. For mild cases and for those that come under treatment just after the onset it is hardly necessary, though in the latter if the pain is very acute it is effectual in relieving the symptoms and it does so quickly.

The details of the treatment will be found in a most instructive paper on sciatica in Dr. Weir-Mitchell's Clinical Lessons on Nervous Disease,[1] where he emphasises as the essential point that the splint must check motion at the hip and the knee. The leg is first carefully and evenly bandaged with a firm flannel bandage from the hip to the knee. A long splint is then applied, the knee being in slight flexion, and bandaged on with flannel bandages and secured round the trunk by two or three broad bands. The heel must, of course, be carefully supported. In my own practice the limb is left untouched for the first three days, or if it is uncomfortable the bandages are taken off and reapplied with as little disturbance as possible. In any case this is done once a day after five days, and after five or six days gentle passive movement of the joints is made at the same time. When the patient has been free from pain for some days, generally at the end of two or three weeks, or longer in a severe case of long standing, the splint is left off by day and reapplied at night. Then the splint is discontinued altogether, the leg being still kept bandaged, and after another week or less the patient is allowed to get up. I have followed Dr. Weir-Mitchell in the above stages of treatment and in taking the absence of pain as the indication to pass from one to the other, and also have followed his valuable caution that when a patient with sciatica first gets up he should stand or lie but not be allowed to sit. When the splint is first left off by day massage of the limb may generally be begun and as in these severe cases the muscles are flabby and wasted it is of great advantage in hastening the restoration of the use of the limb.

I may briefly mention, without going into details, the result of the last 12 consecutive cases of severe sciatica treated in hospital in this way. 11 of the patients were men, their average age being 49 years. The longest time the disease had lasted was 21 months and the shortest time was seven weeks. The average duration before coming into hospital was 23·6 weeks, the average duration of treatment in hospital was five and a half weeks, and the average time from admission until the splint was left off entirely (by night as well as by day) was 25 days. As showing that the cases were severe I may point to the duration, the facts that from the great pain caused by movement four of the patients were carried in unable to walk at all and a fifth could only hobble a few steps with help, that in ten the muscular wasting was marked, and in four there was defective sensation on the outer side of the leg.

Ten patients were cured. One had a severe relapse some weeks later but was cured by a second course of treatment. One was not relieved; he was a restless, impatient man and would not submit to keep the splint on. It will be noticed that the patients only stayed a short time in hospital after they were allowed to get up; a few of them attended for a short time afterwards as out-patients in order to go on with the massage. It seems to me that the result in these cases as to cure and as to the duration of stay in hospital—the latter an important consideration both to the hospital and to working-men patients—is satisfactory.

In patients of the well-to-do classes I have had equally good results. A cure was effected in one man who had suffered from sciatica almost continuously for ten years and he has remained free from pain and able to walk about since the treatment four years ago. In his case the time under treatment was longer than in those given above.

The restraint of the splint is trying to nearly all the patients and extremely irksome to some and the pain may be considerable for the first 24 to 48 hours. With some patients considerable persuasion is required during the first two or three days to induce them to go on with the treatment. A hypodermic injection of morphia is often necessary on the first night and sometimes on the second, but not, in my experience, afterwards. By the third to the fifth day there is great relief and the patients begin to sleep well; indeed, in favourable cases the acute pain is not felt after the third day. If the pain persists it often does so behind the outer malleolus of the ankle or in the foot. This sometimes means that a readjustment of the support is required.

In the more neurotic patients who come into the hospital and in private patients one of the chief difficulties is at first flatulent dyspepsia. Many sufferers from sciatica have already been troubled with this before they come under treatment and it is then aggravated by the enforced rest. Very careful feeding and a light diet are therefore better in all cases at first and afterwards the latter can be gradually improved, for as liberal a diet as the patient can digest is generally advantageous. Lastly, care must be taken that the bed is flat and even and that there is a firm basis of support under a flat mattress. The limb must be absolutely at rest in its whole length and failure to secure this will prevent a successful result. A short course of massage, tonics, and cod-liver oil are advantageous to complete the cure.

I think I have given a fair account of my experience of this method of treatment, and if I have seemed unduly to emphasise small details it is because they are essential, as in many other matters, to success.

Clifton.

A CASE OF

INFANTILE ACUTE ECZEMA; HÆMATEMESIS; DUODENAL ULCER; DEATH.

BY HUGH HOWIE BORLAND, M.B., C.M. GLASG., D.P.H. CANTAB.,
DISTRICT PHYSICIAN, GLASGOW MATERNITY HOSPITAL.

I DESIRE to put this case on record on account of the unique character of the lesion and the fact that I have been unable to find in the literature of the subject a recorded case of duodenal ulcer following eczema, which I believe in the present case are related to each other and analogous to the cases of duodenal ulcer following severe burns.

The patient was a baby, aged eight months. At birth he was well nourished and fully developed He was breast-fed till seven months old. When about two months old he began to suffer from eczema capitis which persisted more or less during the latter months of life. Vaccination was performed at the fifth month; this ran a normal course and had but little influence on the eczema. About the sixth month the face became eczematous with considerable leeting. The left submaxillary gland became swollen and the skin became inflamed as if suppuration was imminent. The swelling, however, subsided by resolution. When seven months old the child was weaned, as the mother at that time was suffering from acute rheumatism. The artificial diet—Mellin's food and milk—on which he was put did not do so well as the mother's milk. On April 2nd, 1903, when eight months old there was an exacerbation of the eczema which took on a virulent form, affecting the head, the face, the neck, and to a slight extent the trunk. From this time onwards the child seemed to go back in every way; soothing applications failed to arrest the intensity of the affection. The patient, previously happy and contented, became peevish and fretful. On the 3rd I saw him and found that the state of the head and face was becoming rapidly worse, but the uption over the trunk had by this time faded entirely. The mperature was subnormal; the pulse was small and 140 [illegible]; the respirations were 30; and the feet and hands [illegible] face and head for the first time [illegible]. *The eyes could not be kept open* ving to the œdematous swelling of the eyelids which had pervened. I found on cleaning away purulent exudation om the closed eyes that the skin was abraded with the entlest swabbing. On the 5th I called in the morning and ound the child asleep in his father's arms; the discharge om the head had *exuded copiously on to the father's shirt*-eeves. When I removed the shawl which was adhering to e head of the little patient I found that the scalp was mply reeking with vapour. I observed further that the aracter of the eruption had undergone a change: the sicles or pustules were now enlarged to the size of a split a; *those were purulent, raised, discrete, and impetiginoid.* esides the mass over the scalp and brow there was an tension of the pustules to the cheeks, the chin, and to a less egree to the neck, but there was still no eruption on the unk Towards evening the child rapidly became worse and t 3 A.M. on the next morning he vomited some blood and om this time the motions were tarry. He drew up his little gs continually and often passed his hands down on the bdomen as if in pain. There were considerable vomiting nd retching. On the 6th the patient had a restless day nd at midnight he seemed to be sick and vomited milk on vo occasions. The bowels were moved just about the same me; the motions were again tarry. He then vomited "some ark-like material." The child's hands were clenched, he y much distressed, and the feet were cold. On the 7th, t 1 A.M., he vomited some blood which was red in colour. n order to relieve the retching a poultice was placed over e stomach and sips of iced water were given by the mouth. *e settled down and was quiet thereafter for several hours.* uring the day, however, retching of a severe nature eturned. He became very restless; at 5.30 P.M. he was oking very ill; the head and face became bluish black. is strength was slowly slipping away and a gurgling sound as occasionally heard. A few sips of whisky and iced *ater had been given to him during the day.* At 10 P.M. he omited a single mouthful of bright-red blood. There was o special retching before this last and fatal vomit, but ubsequently he spat a little and lay down quietly for some me apparently in a collapsed condition. When raised up t any time he cried as if in pain and at times placed his *ft hand over the left side* of the abdomen. He was laid own on his right side about 1 A.M. and at 2.30 A.M. a movement was heard of something passing down the bowels. [illegible] after which he became quiet, [illegible] twitching of [illegible] h.

I have to record my thanks to Dr. John Anderson, athologist to the Victoria Infirmary, Glasgow, for making he post-mortem examination for me and I append a ummary of his report. From external appearances the atient was a well-developed and well-nourished child. igor mortis was pronounced. The pupils were equal and f medium size. Eczema of the face and head was present. s to the thorax, the pericardium was healthy. The eart was of normal size and appearance, the chambers resenting healthy characters. A small quantity of clot as found in the right ventricle. All the valves preented normal and healthy appearances. There was a iny patency of the foramen ovale. The heart muscle as of good colour and consistence. The lungs were nonadherent and apart from a slight degree of congestion of the ases presented remarkably healthy appearances. With egard to the abdomen a few ounces of blood-stained fluid ere found in the general peritoneal cavity. No evidence of eritonitis could be found. In the lesser sac of the perioneum was found a large-sized piece of clot filling pracically the entire space. The posterior wall of the stomach nd surface of the pancreas on which it rested showed resence of fibrinous exudation. A round ulcer situated on he posterior wall of the duodenum just beyond the pylorus as made out The ulcer had perforated and the perforation as of about the size of a split pea with punched-out edges nd directed towards the lesser sac of the peritoneum (see igure). The stomach contents were chiefly of the nature of ltered blood. The stomach presented healthy appearances; he mucous coat was rugose and slightly congested. The ntestine was examined throughout and apart from bloodtaining of the contents showed healthy appearances. The liver was of normal size and slightly cloudy in appearance. The spleen was healthy. The kidneys and adrenals were healthy in appearance.

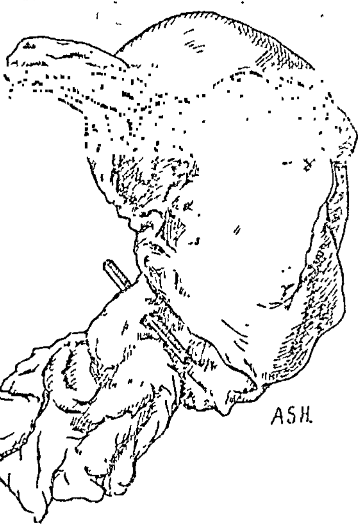

Illustration showing the stomach and duodenum of the child. The place where the perforation occurred is indicated by the wooden probe *in situ*.

The skin of a child is relatively greater in area than that *of an adult in its ratio to the body weight, hence a cutaneous* lesion predisposes infants to constitutional disturbances of greater intensity and may be expected to tell more severely upon them. This may be due to impairment of the function of the skin, to nerve irritation, to destruction of red corpuscles or leucocytes, or to absorption of toxins from the *disintegration of the blood corpuscles.* I am disposed to regard the occurrence of the duodenal perforation in this case of eczema as due to the same contributory causes which we [illegible] of burns. In both there is a like [illegible] n and the soluble fibrin [illegible] entrance to the circu-[illegible] of emboli which results [illegible] the duodenal mucous membrane.

Cases of duodenal ulcers have been recorded after burns as already mentioned, after frost-bite, and in erysipelas, pemphigus, and septicæmia. In those due to infective processes bacterial influences obviously play an important part.

The etiology of duodenal ulcer and its relationship to cutaneous burns.—As bearing upon the above case it is interesting to consider the remarkable coincidence of burns of the skin with ulce[illegible] subjects first observe[illegible] less than ten cases; [illegible] subject has been investigated by several observers, especially in England, with the result that though the occasional appearance of an ulcer after an extensive burn has now been well established the occurrence is certainly very rare. In 125 cases of severe burns Holmes[3] *found the duodenum* ulcerated in 16 and other portions of the intestine in two. The earliest appearance of the ulcer was *from four to six* days after the burn. Perry and Shaw[4] noticed it five times in 149 necropsies of cases of burns. It is further established that these ulcerations occur chiefly in young subjects and more especially when there are extensive burns of the trunk; that the ulcer occurs in the second or inflammatory period of the burn; and that *before ulceration occurs there is marked* congestion followed by hæmorrhagic infiltration which affects

---

[2] Dreschfeld: Allb[illegible]

[3] *Holmes:* [illegible]

[4] Perry and Sha[illegible]

other parts of the alimentary tract besides the duodenum. In several cases the lesion did not go beyond a hæmorrhagic infiltration; in other cases, an ulcer forms which may lead to a perforation or to profuse hæmatemesis. The formation of the hæmorrhagic infiltration is most rationally explained by a septic embolus and the change into an ulcer by the action of the gastric juice. The nature of the ulcer is similar in character to the gastric ulcer, round or oval, punched-out appearance, with little inflammation of the periphery, and microscopically shows the same condition—more of a necrosis than inflammatory round cell or new cell formation. The ulcer is situated in the first part of the duodenum and above the bile papilla and is therefore classifiable with the gastric ulcer. It falls, then, under the same group of causes. It may arise from mechanical, chemical, thermal, &c., agencies; bacterial necrosis has been said to play an important part, while in the case of burns the destruction and emboli formation of red corpuscles have been assigned an important place.

Micro-organisms have been brought forward as the cause of gastric ulcer. Letulle[5] found numerous streptococci in the veins of the submucosa and of the uterus in a case of recent ulcer of the stomach which appeared during the course of puerperal septicæmia. Pure cultures of these injected into guinea-pigs also caused ulcerations in the stomachs of the animals and these threatened to perforate the walls of the distended organ. Letulle obtained the same result in four cases with staphylococcus pyogenes aureus cultivated from various abscesses and in one case with the microbes of dysentery. Experiments by Ponfick and others have shown that in animals extensive scalds will cause a destruction of red blood corpuscles similar to that seen on injecting toluylendiamin. Dr. W. Hunter succeeded in producing extensive ecchymoses and ulcers of the duodenum in dogs by injecting toluylendiamin and suggested, as a probable explanation of the duodenal ulcer in burns, the secretion, with the bile, of a poison which causes the ecchymoses and ulceration. Virchow's view that the process may result from plugging the nutrient artery of the part, either by an embolus or by a thrombus, and that the infarct so produced is destroyed by the gastric juice, has gained general acceptance. There is obviously a local disturbed nutrition over a circumscribed area. The corrosive action of normal gastric juice plays an essential rôle in attacking the spot deprived of its vascular supply just as under favourable conditions it leads to softening and digestion of the dead tissue of the stomach. If the gastric juice meanwhile has become hyperacid and cannot be neutralised till it meets with the pancreatic secretion, this will readily explain why round ulcers are so prone to occur in the duodenum. Eostein,[6] making use of a discovery of Schiff, produced gastric hæmorrhages and corroding ulcers, and even perforation, by injury to the anterior corpora quadrigemina and it has been assumed that the excessive production of acid secretion in these cases was due to cerebral irritation.

The relationship of the eczema to the lesion—It was noticed in the last three days of the child's life that the eczema was characterised by a virulent exacerbation—that the septic condition of the skin had become intensified, enabling the flora of the skin to assume fresh activity from the increased pabulum. The lesion had merged into eczema pustulosum—eczema impetiginoides due to secondary inoculation of the inflamed skin by pus cocci; this is to be distinguished from impetigo contagiosa by the fact that the pustules in the latter disease occur on healthy skin and not on an already inflamed surface. When the eczema of the child had passed into the acute pustular form it is a reasonable theory to suppose that septic absorption supervened from bacterial toxins and that these, acting as a source of irritation on the central nervous system, produced greater acid secretion in the stomach and duodenum. The cutaneous lesion of this nature brings about an alteration in, and destruction of, the blood corpuscles through the superficial inflammation of the skin, followed by necrosis of the superficial layers of the epidermis and the prolonged secretion of serum and pus

Treatment.—Surgical intervention was in this case beyond consideration after the diagnosis was assured. Had the case not presented such grave features surgical interference would have been worthy of suggestion and adoption in view of the absolutely hopeless prognosis of ulcer of the duodenum after perforation, although it must be conceded that the results of such operations offer nothing to boast of.

Glasgow.

THREE CASES OF PERFORATED GASTRIC ULCER; RECOVERY AFTER OPERATION.

BY FREDERICK C. WALLIS, B.A., M.B., B.C. CANTAB., F.R.C.S. ENG.,
ASSISTANT SURGEON, CHARING CROSS HOSPITAL; SURGEON, METROPOLITAN HOSPITAL, ETC.

CASE 1.—A single woman, aged 34 years, was admitted into the Metropolitan Hospital on Jan. 1st, 1902, at 9 P.M. The patient had been seized with sudden pain in the epigastrium at 9 A.M. on the same day and was much collapsed. She was seen by Mr. Reginald Brown who gave her morphia; she was also seen by a surgeon in the afternoon. Towards evening the pain returned, the abdomen became rigid, and the pulse rate increased. There was a past history of anæmia and indigestion for years but there had never been any hæmatemesis. When seen at the hospital she was not in great distress but was evidently well under the influence of morphia. The abdomen was not moving at all and on the upper and left side where the pain was complained of the muscles were very rigid. Resonance was unaltered all over; the liver dulness was normal. No dulness was present in the flanks.

Operation was performed at 11.30 P.M. on the day of admission. Chloroform was the anæsthetic used. An incision was made in the mid-line above the umbilicus. There was no sign of general peritonitis or free gas on first opening the abdomen but on reflecting the omentum to expose the posterior surface of the stomach there was a small escape of gas. A perforation was found in a small lymph-covered area on the posterior wall, near the cardiac end of the lesser curvature, about two millimetres in diameter. There was very little escape of stomach contents. The perforation was sewn up by invagination with Lembert's sutures. Any lymph and fluid were sponged off the neighbouring peritoneum and no fluid was used in the abdomen. The abdomen was closed and no drain was employed.

The patient made an uninterrupted recovery. She sat up in bed on the second day, was on the couch the middle of the third week, and left the hospital at the end of six weeks in better health than she had been for years. She was seen in September, 1902, and in July, 1903, when she was as well as could be wished. The following was the diet used while in hospital. Rectal feeding was begun on the morning after the operation with three and a half ounces of peptonised milk every four hours and one yelk of egg. Nothing was given by the mouth until the fifth day after the operation when small quantities of water were allowed. On the next day one drachm of whey was given every hour; occasionally the same amount of beef-tea was given instead. This quantity was gradually increased until at the end of three days four drachms were given every hour. Very gradually the amount given by the mouth was increased and the rectal feeding was discontinued. On the nineteenth day after operation baked custard was added to the diet and the enemata were discontinued entirely. On the twenty-third day a small amount of boiled sole was given. On the twenty-sixth day the note reads: "Diet as follows with slight variations daily: Breakfast, 6 A.M., milk, thin bread-and-butter; luncheon, 9 A.M., milk or beef-tea and jelly; dinner, 12 noon, boiled sole, bread and-butter, custard with milk or water; tea, 3 P.M., milk, bread-and-butter, sponge cake; and supper, 7 P.M., beef-tea or milk and custard or jelly. Total, one pint of milk and half a pint of beef-tea in the 24 hours." On the twenty ninth day two lightly boiled eggs were added and a week later minced chicken was given. On Feb. 14th the patient went home taking ordinary diet except meat.

CASE 2.—The patient, a woman, aged 21 years, was admitted to hospital on Jan. 24th, 1902. She had felt sudden pain in the epigastrium on Jan. 21st; this had been constant ever since but it recurred more violently on the morning of the day of admission. On this day she vomited three times.

---

[5] Letulle: Origine infectieuse de certains Ulcères simples de l'Estomac ou du Duodenum, Comptes Rendus, tome cvi., No. 25.

[6] Ebstein: Experimentelle Untersuchungen über das Zustandekommen der Blutextravasate in der Magenschleimhaut, Archiv für Experimentelle Pathologie, Band ii., S. 183.

The bowels had not acted since Jan 20th She had suffered from anæmia and dyspepsia for three or four years but there had been no hæmatemesis Her condition on admission was as follows She was fat and anæmic and looked ill The temperature was 101° F, the pulse was 120, and the respirations were 40 and thoracic only The abdomen was rigid with no movement; it was moderately distended; great pain and tenderness were present in the left hypochondrium; there was dulness in the left flank The liver dulness was unaltered

Operation was performed The abdomen was opened but contained no free gas There was no general peritonitis The area in the lesser curvature of the stomach near the cardiac end posteriorly was covered with lymph A little gas escaped on disturbing these parts The perforation could not be found until a linear incision was made through the anterior surface of the stomach when on inserting the finger an ulcer with a tiny perforation was found high up on the posterior surface of the lesser curvature near the cardiac end The perforation was sutured, as was also the incision The peritoneum was wiped out, no lotion being used The abdominal wall was closed with a single row of silkworm gut sutures Four hours after the operation the patient was propped up with pillows and on the next morning she sat up with a bed rest, feeling quite comfortable She vomited once after the anæsthetic. The convalescence of this patient was quite uneventful The diet was practically similar to that in Case 1 The patient has been seen since and is perfectly well

Both these cases were under the care of Mr Brown before coming into the hospital and on admission both were well under the effect of morphia. In neither instance were the abdominal symptoms distressing nor was there much distension The acute onset, the localised pain, and the tension of the abdominal muscles were the main symptoms on which abdominal section was performed In Case 2 much time was saved by the incision into the stomach and a thorough knowledge of the ulcer was obtained, whilst the closing of it was facilitated Valuable information and assistance may be obtained by this method which practically does not add any risk to the operation More use should, I think, be made of it than has hitherto been the custom No fluid was used to wash out the abdomen and any fluid that was already there was lightly sponged out with Gamgee sponges the peritoneum being interfered with as little as possible The patients were placed in a sitting posture in bed as soon as they had recovered from the anæsthetic The after treatment and diet which were carried out by Dr J A Nixon (my late house surgeon) were, I think, the best possible and had largely to do with the success which followed the operations

CASE 3 —The patient, an anæmic looking young woman aged 19 years, was admitted into Charing Cross Hospital on May 1st, 1903, suffering from perforated gastric ulcer She had been in good health until the past few weeks, during which she had been suffering from anæmia She had not had any pain after meals except occasional heartburn About a week before admission she had first experienced subacute pain in the left hypochondriac region; this had no relation to food and did not cause vomiting and was put down to a strain On April 30th, at 4 30 P M, about four hours after her midday meal, she was suddenly seized with acute pain in the epigastric and left hypochondriac regions and became collapsed and was helped to bed When seen by a medical man at 9 30 P M she was in great pain The pulse was 120 the epigastrium was extremely tender, and vomiting was frequent A small amount of morphia was injected and she had a little sleep, but on waking the pain and vomiting returned This condition of affairs continued until she was admitted to the hospital at 5 P M on May 1st evidently in great pain The pulse was 140 and the respirations were 30 On examining the abdomen it was found to be slightly distended and extremely tender

Operation was performed 27 hours after the first onset The abdomen was opened by a median epigastric incision No gas was noticed to escape but some clear blood stained fluid came out of the peritoneal cavity; this was not offensive and, in fact, was odourless On lifting up the margin of the liver a quantity of blood stained turbid fluid came from the space in front of the lesser omentum A perforation was seen on the stomach near the lesser curvature a little to the left of the pylorus, the perforation was one third of an inch in diameter and the surrounding tissues were infiltrated and very friable The perforation was closed and was then sewn twice over with interrupted Lembert sutures The liver and surrounding structures in the neighbourhood of the lesser omentum were carefully wiped A gauze drain was passed down to the stomach and the incision was closed with one row of interrupted fishing gut sutures The operation was fairly well borne A saline and beef tea enema was given before the patient left the operation room

This patient eventually made a good but somewhat protracted recovery The after treatment in this case was much the same as in the former two cases but a certain amount of intestinal irregularity caused at times a quick pulse and a rise of temperature which it was feared might mean the starting of a subphrenic abscess This, however, all cleared up and the patient went to the convalescent home two months after her operation

Harley street, W

A NEW ETHYL CHLORIDE APPARATUS AND METHOD

By G W BAMPFYLDE DANIELL, M R C S ENG,
L R C P LOND,

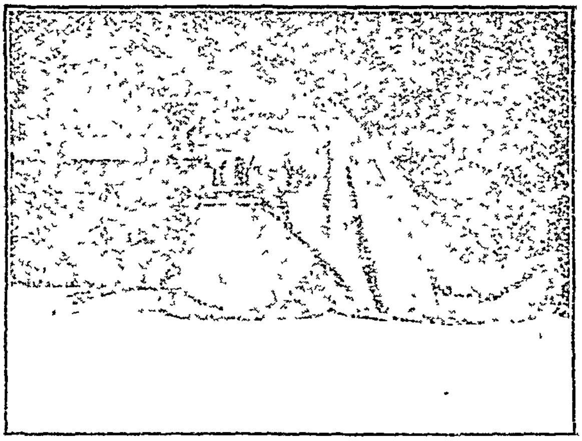
LATE ANÆSTHETIST TO THE TOTTENHAM HOSPITAL ETC

SINCE chloride of ethyl has of late been receiving so much attention as a general anæsthetic there has resulted a variety of special inhalers for its administration, each of which claims certain advantages I venture to think that the most convenient as well as the most simple in use is that so easily made by attaching together the facepiece and angle mount of an ordinary Clover's portable ether inhaler and introducing the chloride of ethyl through an orifice at the end of the angle mount If it is desired to give this agent as a preliminary to ether instead of nitrous oxide the ether chamber is, of course, retained in its place

In THE LANCET of July 18th, 1903, p 168 Dr T D Luke has explained and illustrated his inhaler which is of the above mentioned pattern except that the ordinary tap for nitrous oxide has been removed and the hole in the angle-mount is closed with a boxwood plug In most of the other inhalers I have seen and used the estimated dose of ethyl chloride has first to be projected on to a more or less extensive surface of lint, cotton-wool, or sponge which is situated close to the patient s nose and mouth and then the mask is rapidly applied In others a capsule is broken—containing either three or five cubic centimetres of ethyl chloride—inside the inhaler

The objections to the former class of inhalers are that a certain amount of the fluid rapidly evaporates and is lost for anæsthetic purposes, and consequently an unknown quantity of the agent is given Also, freezing takes place inside the mask and often close to the patient s nose and mouth The objection to the capsules is that there is too much restriction of dose In the case of children one and a half to two and a half cubic centimetres are often enough, and in adults five cubic centimetres are often more than are necessary for one inhalation Again, for prolonged administration a much larger amount than five cubic centimetres may be required and it would be inconvenient and wasteful to be frequently breaking capsules The disadvantage to both methods is that the patient is subjected to a concentrated vapour of the full dose immediately the mask is applied to the face This is to many patients alarming, especially to children and nervous subjects, and not infrequently causes hampered breathing, coughing, choking, struggling, and consequent delay in the induction of anæsthesia

Having used this "Clover method a number of times I find the following modifications of great advantage and venture to submit them to the consideration of administrators Instead of the hole and boxwood plug in the angle mount I retain the ordinary tap with metal tube continuation, commonly found on the Clover s angle mount and used for gas in the nitrous oxide ether sequence The tap is easier to manipulate than the plug and cannot get lost. Also owing to the construction of some of the trigger-valved ends of the ethyl chloride bottles it is easier to get in the fluid through the projecting end of the tap than through a hole flush with the surface of the angle mount, especially if the patient is inclined to move At the commencement of the inhalation, instead of projecting the ethyl chloride through the tap directly from the bottle, I first measure out a definite quantity into a small tube made of thick glass, which for the sake of accuracy I have marked in three, four, and five cubic centimetre graduations. To this small measure-glass is attached a short piece of red rubber tubing, by means of which it is attached to the end of the tap of the angle-mount (vide illustration).



In the case of a patient sitting up in the dentist's chair the position of the tube in relation to the facepiece is as shown in the illustration and the tap may with advantage be closed. The tube being downwards, no ethyl chloride will escape and no smell will be noticed if the tap is closed. The mask having been accurately adjusted to the patient's face a short period of to-and-fro breathing is first permitted, the tap is then opened, and the angle mount, with its tube, is rotated from the vertical position—with the administrator's right hand—until it is almost horizontal. The rotation is now conducted gradually so that the fluid will run very slowly out of the glass phial through the tap and metal tube into the bag. If this is done at first slowly the patient will soon get accustomed to the dilute vapour and most of the fluid, at least at first, will evaporate on its way through the tap and metal tube, very little entering the bag in a liquid state. If there is a tendency to holding the breath or to coughing the angle-mount can be rotated back again, thus limiting further evaporation of the ethyl chloride until the symptoms subside; it can then be rotated upwards again and the flow continued until the tube is empty. With a little care and practice there will only on rare occasions be any trouble during induction

In the case of a patient in the recumbent position it is sometimes better to have the charged tube apart but close at hand. The facepiece having been adjusted the tap is then opened and the tube fixed on, and all that then will be necessary is to tip up the tube very slowly, which is easily done on account of its rubber attachment to the tap. Should more ethyl chloride be required—and this is most likely to occur in the case of full-blooded muscular men and alcoholics—the tube can be removed and recharged with a definite dose, or more may be projected directly from the bottle through the tap. If desired, the bag can be first filled with nitrous oxide and the patient permitted to inhale it until commencing unconsciousness, then the rubber gas tube can be detached and replaced by the charged phial—which should be in this case rather more quickly emptied—and full anæsthesia rapidly follows. By replacing the ether chamber this method can be used to give ethyl chloride as a preliminary to ether just as well as the nitrous oxide-ether sequence, the only thing necessary being the little glass phial with its rubber tube The idea of the glass tube I have from Dr. F. W. Hewitt who uses it with his special gas apparatus to give nitrous oxide and ethyl chloride mixed. The metal tap and tube of the angle mount can with advantage be made larger than is generally found and that of mine (supplied to me by Mr J. H Montague of New Bond-street, London, who also makes the glass tubes) is very much larger.

The following is a summary of the advantages of this inhaler and method of administration: 1. A measured quantity of the anæsthetic fluid is given, varying according to the age of the patient and taking into consideration the time of anæsthesia required, the nature of the operation, &c. This gives accuracy of dosage and is useful for making observations and notes for future reference. It should also help to insure against an overdose. 2. The ethyl chloride can be given *gradually* and that *after* the facepiece is adjusted; this prevents coughing, holding the breath, &c., and produces a satisfactory induction. The tube need not be emptied if satisfactory anæsthesia is likely to be produced by less than its contents. 3. More can at any time be added if necessary, either by projecting the fluid through the large open tap or by measuring off more in the tube; also, either can be done without having to remove the facepiece which is an advantage in some cases. 4. Movements on the part of the patient before anæsthesia is complete are of little consequence as the charged tube can first be fitted on, which it is desirable to do in the case of children and nervous patients who are likely to struggle or to resist. 5 In the case of struggling it may be better to empty the tube more quickly, and then both hands of the administrator are available to hold the mask and to steady the patient. 6. If the tap is turned off before the tube is fixed on the patient will not experience the slightest smell of the narcotic when the mask is applied. This is of importance in nervous patients. 7. A perfectly free air-way, no lint, sponge, or wool to breathe through, and no *freezing* vapour near the patient's mouth or nose, as all evaporation takes place in the metal tube and rubber bag. 8 Nitrous oxide can be given as a preliminary, and by retaining the ether chamber ethyl chloride can be given before the ether, all that is necessary being the glass tube. 9 Bromide of ethyl could be given with advantage by this apparatus, as it is important to be able to measure carefully the quantity of the drug. It would be as well to have a larger graduated phial in this case. 10 Economy in the amount of the anæsthetic used.

I have given ethyl chloride by this method and apparatus using the paper bag—as invented by Mr. Rickard W. Lloyd and made by Messrs. Barth and Co.—with satisfactory results and recommend its use instead of the rubber one in the case of patients suffering from tuberculosis. In conclusion, I would state that up to the time of writing I have given ethyl chloride over 150 times by this method and in not a few cases somnoform; also a number of times in conjunction with ether.

Edinburgh.

TWO CASES OF CÆSAREAN SECTION.

BY ARTHUR H. N. LEWERS, M.D., F.R.C.P. LOND.,
SENIOR OBSTETRIC PHYSICIAN TO THE LONDON HOSPITAL.

IN the course of last year I had two cases of Cæsarean section for obstruction due to fibroid tumours. These cases did well both as regards mother and child and an account of them was published in THE LANCET.[1] Since then I have had two cases of Cæsarean section for pelvic contraction, which are typical of the two classes in which Cæsarean section is performed for this cause.

The first case is an example of the group in which the fact that the pelvis is contracted and the degree of the deformity have been ascertained some long time before labour is expected, and where a date, generally about a week before full term, has been fixed for the performance of the operation. In such cases every opportunity is afforded for operating in the most favourable circumstances; the patient is thoroughly prepared beforehand as in other cases of abdominal section and the preparations for the operation itself can be made as carefully as in ordinary cases of ovariotomy. The patient has to stand the effects of the operation but she has not been worn out beforehand by prolonged labour nor has she been subjected to the risk of infection by vaginal examinations, with, perhaps, fruitless attempts at artificial delivery through the natural passages. Provided the operator is accustomed to abdominal work and familiar with the special points that require attention in this particular operation, especially as regards the proper method of suturing the uterine wound, Cæsarean section in the circumstances under consideration is an operation of little risk at the present time. Formerly it was thought to be disadvantageous to operate before labour pains had started, either spontaneously or after the induction of labour, for it was believed that if labour had not started the uterus would not contract well after Cæsarean section. This objection has now proved to be merely theoretical and, in fact, in cases of Cæsarean section performed before the onset of labour the uterus does contract as well as after a normal delivery.

---

[1] THE LANCET, Jan. 17th, 1903, p. 157.

In the second case we have an example of the class in which nothing has been known of the existence of pelvic contraction till labour has been some considerable time in progress and where unavailing efforts to effect delivery with the forceps have been resorted to. Such a combination of circumstances is generally considered to add greatly to the danger of Cæsarean section. While I am far from disagreeing with that view of the matter I think that the danger may be easily exaggerated. Much must necessarily depend on the exact circumstances of the particular case. The time that the second stage of labour has lasted, the state of the patient at the moment, and the probability or otherwise that the preceding vaginal examinations or manipulations have been made by someone who may be trusted to have scrupulously observed the principles of asepsis are the chief factors to be taken into account. The suitability of the surroundings for the performance of an abdominal section under aseptic conditions is also, of course, a matter of the first importance. Again, the vitality of the child as evidenced by the state of the fœtal heart sounds must be ascertained as well as possible. If the heart sounds have their normal frequency the chances are that the child's vitality is so far unimpaired; on the other hand, if the heart sounds are much slower than normal the child is probably already in a critical condition as a result either simply of the prolonged labour or of the damage it has undergone from attempts to deliver with the forceps. In this case the patient, who had had one previous confinement, had been some 28 hours in labour and two attempts to deliver with the axis-traction forceps had been made before she came under my observation. The fœtal heart sounds were easily heard and had about their normal frequency. Yet although the child's heart was still beating after delivery all attempts at resuscitation unfortunately failed. This is, I think, to be ascribed in all probability to the previous attempts at forceps delivery. Obviously, then, it is most desirable to miss no opportunity of recognising contraction of the pelvis early in pregnancy, for in that way if delivery has to be effected by Cæsarean section the risk to both mother and child is very much reduced.

CASE 1.—The patient, aged 29 years, was admitted into the London Hospital on March 6th, 1903, for the purpose of having Cæsarean section performed. She had been married four years and had had two confinements. In the first labour, which took place on April 23rd, 1900, she was delivered of a full-term stillborn boy. The presentation was a footling and the child was said to have been "suffocated." No instruments were used. The puerperium was normal. In her second labour on July 20th, 1901, she was delivered with forceps of a stillborn boy who was the first of twins. On the 22nd she was brought up to the London Hospital in labour with the second child. Delivery was effected by cephalotripsy at 7 A.M. on the same day. Her temperature on admission was 100° F.; at noon she had a rigor and the temperature rose to 106°. On the 25th she had another rigor with a temperature of 106 5°, the pulse-rate being 128. On August 2nd there was pain in the right hypochondriac region and there were physical signs of pleurisy. Up to the 6th there was marked pyrexia with nocturnal elevations. On that day she had another rigor, the temperature reaching 106°. On the 10th a sausage-shaped swelling was felt on the right side of the vagina close to the vulva. This proved to be an abscess and it was opened on the 12th On the 14th a superficial abscess on the buttock was opened; it communicated with that in the vagina. A large quantity of fœtid pus was evacuated. On the 21st a firm swelling occupying the right iliac region was noted. The uterus was almost fixed. The temperature at this period varied from 99° to 101°. The cellulitic swelling in the right iliac region did not suppurate. It gradually disappeared, the temperature came down, and the patient went to a convalescent home on Sept. 14th. She came to the London Hospital in November, 1902, and was then found to be about six months pregnant. She was told that she could either have labour induced at the seventh or the eighth month or that she could go to her full time and have the child so delivered that there would be little or no probability of a future pregnancy. She chose the latter alternative and was admitted on March 6th, 1903, under the care of Dr. G. E. Herman. Shortly afterwards, owing to Dr. Herman's absence from the hospital, the patient came under my care. A consideration of the dates led me to believe that March 19th was the date on which labour might be expected and accordingly I decided to perform Cæsarean section a week beforehand—namely, on the 12th. The measurements I took of the pelvis were as follows: between the anterior superior iliac spines, 9 inches; maximum distance between the crests, 10 inches; the external [illegible]

three and a half inches. I performed Cæsarean section on the afternoon of March 12th, Mr. R. Norman, the senior resident accoucheur, assisting me. The child, a girl, was extracted alive and soon cried vigorously. The uterine wound was sutured with deep and superficial sutures of silkworm gut. The deep sutures were of course passed through the peritoneum and muscle only. The left Fallopian tube was found to be occluded but not dilated and it was not interfered with. A portion of the right Fallopian tube was pinched up, tied, and the distal portion removed about one-eighth of an inch beyond the ligature. The patient stood the operation well. The temperature at 8 P.M. was 100·2° and the pulse was 114. After 24 hours the temperature was normal and the pulse was 80. The patient made a good recovery; the temperature remained normal, except on one afternoon when there was a service in the ward. It fell on the next morning and did not rise again. All the abdominal sutures were out by the tenth day. The patient got up at the end of the third week and left the hospital shortly afterwards with her child, both perfectly well.

CASE 2.—The patient, an alien immigrant who spoke no English, was admitted from the outdoor maternity department into the London Hospital under my care on July 19th, 1903, at 12.30 A.M. She had been in labour since the 17th at 10 P.M. It was difficult to get much information as to her previous history. She was believed to have had one child previously in Russia. It was said to have been small and to have been delivered with forceps after a very difficult labour. On the present occasion two attempts had been made to effect delivery with the axis-traction forceps before I saw the case. The head, which lay in the second vertex position, could not be made to enter the brim. When I saw her at about 1 A.M. she was having strong pains almost every minute, the vulva was very œdematous, the os was fully dilated, and the head was in the position just mentioned. I measured the pelvis carefully and found that the distance between the anterior superior spines was 8 inches, the maximum distance between the crests was 9⅜ inches, the external conjugate was 6⅝ inches, and the diagonal conjugate was 3⅞ inches. The true conjugate was judged to be about 3¼ inches. The fœtal heart sounds were easily heard and they seemed to be normal. The alternative methods of delivery that were considered were craniotomy, symphysiotomy, and Cæsarean section. As the child was alive and the mother's condition was fairly good I excluded the first. The choice between symphysiotomy and Cæsarean section was difficult. The œdematous condition of the external genitals influenced me to some extent against symphysiotomy and I decided upon Cæsarean section. The patient was in a very dirty condition on admission. The skin of the abdomen was first thoroughly washed with soap and water and afterwards was rubbed with a solution of biniodide of mercury in spirit; the part of the skin in relation with the operation was also thoroughly rubbed with ether. I then performed Cæsarean section assisted by Mr. A. L. Matthews, resident accoucheur. As compared with the operation when undertaken before the rupture of the membranes, it was noteworthy in the present instance how closely the wall of the uterus was applied to the child's body. On that account more care than usual was necessary in cutting through the uterus to avoid injuring the child. The placenta was attached under the upper half of the uterine incision. The child was extracted rapidly without difficulty but although the heart could be seen to be beating all efforts at establishing respiration were unsuccessful. The uterine wound was sutured with silkworm gut, an attempt was made to sterilise the patient as in the preceding case, and the abdominal wound was closed completely. In this case there was a good deal of distension for the first [illegible] bowels were well opened; [illegible] nt made a good recovery

Harley-street, W.

ON THE ETIOLOGY OF BUBONIC PLAGUE:

AN EPIDEMIOLOGICAL CONTRIBUTION.

BY J. ASHBURTON THOMPSON, M.D. BRUX., M.R.C.S. ENG., L.R.C.P. LOND., D.P.H. CANTAB.,
CHIEF MEDICAL OFFICER OF THE GOVERNMENT OF NEW SOUTH WALES; PRESIDENT OF THE BOARD OF HEALTH, HONORARY FELLOW OF THE INCORPORATED SOCIETY OF MEDICAL OFFICERS OF HEALTH.

OBSERVATION of two epidemics of plague which have occurred at Sydney among whites and in circumstances of population, laws, customs, housing, and food which closely correspond with European conditions has led me, as well as all the members of the public health staff over which I have the honour to preside, to entertain opinions concerning the diffusion of plague which differ fundamentally from those commonly advocated. What the latter are can be most concisely shown by a quotation from the latest work which deals with this subject. I refer to "A Manual of Plague," by Major W. E. Jennings, I.M.S., and I choose it for the purpose not merely because it has been published during the present year but also because it is most carefully written and reflects with great accuracy the views as to the causation of epidemic plague which are all but universally held at this date. The quotation runs as follows: "Our measures for the prevention of plague should be mainly directed against what the strongest evidence points to as the most important etiological factors. The disease is mainly spread by human beings, infected clothing or effects, and ship-borne rats" (chapter x., p. 200), and that the teaching thus indicated is not confined to the English school is testified sufficiently for the present purpose by reference to the extraordinary pains taken to isolate every person who had in any way come into communication with the subject of that case of laboratory plague which recently occurred at Berlin.

The teaching drawn from the first of the epidemics at Sydney directly opposed those views; it was that neither direct nor indirect communication with the sick had borne any share at all in diffusion of the disease, that place-infection almost certainly had not operated to maintain it, and that the sole source of infection for man had lain in rats affected with it. The evidence on which these opinions rested was given in my official report[1] which probably has fallen under the notice of most of those who are specially interested in this subject; however, its contents were also summarised in an article which appeared elsewhere.[2] Its importance lay wholly in positive exclusion of human intercourse and of place-infection as factors in the epidemic prevalence, a point which one author alone has perceived.[3] It lay not at all in the assertion that the sole source of the infection consisted in diseased rats which, though clearly seen by us to be justified, was but imperfectly supported by examples.

Our observations of 1900 have been repeated at two places and, as far as the reports permit judgment, with similar results—namely, at Brisbane, Queensland, by Dr. G. B. Halford[4] during epidemics which occurred in 1901 and 1902, at the same city by Dr. B. Burnett Ham[5] during a further epidemic which occurred in 1903, and at Port Elizabeth, Cape Colony, by Dr. G. J. Blackmore[6] during the earlier part of an epidemic in 1901. All of these writers seem to have been able to exclude the influence of human intercourse and place infection.

A second epidemic began about 15 months after the first had ceased. It afforded the desired opportunity of repeating, checking, and extending the observations recorded in 1900. A result was that the latter were in every respect corroborated. My account of this second epidemic, together with many interesting and important observations by Dr. Frank Tidswell who directs the laboratories of the board, has also been published and is now available to epidemiologists.[7] I do not propose on this occasion, therefore, to offer any summary of its contents; suffice it to say that the opinions thus far referred to have been carried into practice. I do not isolate the sick but allocate wards to them which form part of the infectious diseases division of a general hospital; there they are treated under the same conditions as are cases of measles or chicken-pox in other and adjacent wards in the same inclosure; the only extra precaution which has been taken is that of rendering all the wards rat-proof. Neither do I segregate those who have been in contact with cases of plague (though to this contact with cases of primary plague pneumonia would form an exception), in accordance with an opinion which I have elsewhere expressed—namely, that "contacts" are not such persons, but those who have been closely associated with plague rats.[8] Hence disinfection of clothing, &c., is rapidly done; only the cleansing of houses from rats and the rendering of them less liable to infestation in future are subjects of careful attention. These modifications of the method of managing epidemic plague which elsewhere is still thought necessary have been attended with a great saving of time, anxiety, perturbation of the public mind, and of money, and if the result may be referred to as evidential in relation to the soundness of our conclusions, it can be said to have confirmed in practice the teaching we drew from the epidemiological facts observed in 1900.

Another consequence of these improved conditions was that the business of managing the second epidemic proceeded quietly and steadily, without excitement on the one hand and without opposition to necessary measures on the other. Hence, it became possible to direct attention mainly to examining much more closely than before into the nature of the relationship which existed between cases of plague and plague rats—a matter which, with us, had come to take that position of prime importance which before had been occupied by the questions whether human intercourse and place-infection were in reality among the causes of epidemic bubonic plague. Connexion between the neighbourhood of plague rats and cases of plague was discovered very much more completely than in 1900 and especially precedence of the disease among rats over its occurrence in man was shown by the events noted in many separate localities to have been practically constant. Starting then, from these two latter observations which, for us, have all the weight of facts, I proceeded to inquire by epidemiological methods how communication of the infection from the rat could be commonly effected under the conditions of daily life.

In the rat plague is a septicæmia; certainly some special means are necessary to transmission of the infection from it to man. Now, we know that plague rats can deposit the virus on external objects with the nasal secretion and with the excreta; it is possible, therefore, that it might reach man in one of two ways—(1) by contamination of his food and (2) by casual contact with his skin. The former of these must be summarily dismissed from consideration, for there is practically no pathological evidence that man is infected by feeding. If it be possible, as analogy from experiments made with the lower animals suggests, at all events it has happened so rarely that this mode can have no significance in relation to epidemics. But the pathological evidence that the infection is commonly received by inoculation in the skin is direct, uniform, and clear; all but a small minority of cases in every considerable epidemic are of the bubonic form and all such cases are so caused. Consequently that inoculation is the result of casual contact with deposited virus is at this date very generally held to be the most important cause of epidemics, although (altogether contrary to my experience) deposition is usually ascribed to man, and but rarely, or in quite a minor degree, and always with hesitation, to plague rats. This mode of infection—inoculation in the skin by casual contact with deposited infection—is a possibility which, it may be admitted, has occasionally come into play; but what evidence is there that it is a factor of any practical importance in production of epidemic prevalences of plague? This is the question which I propose to refer to a test of practical experience.

The proof that the infection of plague is communicated to man by inoculation through the skin in the vast majority of cases has been well stated in the report of the Indian Plague Commission.[9] It is, "that primary buboes practically always develop in connexion with lymphatics which originate in the skin." The constant preponderance of "inguinal" or "groin" buboes over others was also shown in the same paper to stand in relation to the larger area of skin which drains through the lymphatic glands of the groin. Analysis of returns which represented 5442 cases of bubonic plague showed that the ratio in which buboes occurred in the lymphatic glands of the head and neck, the axilla, and the groin respectively was nearly the same as the ratio which the skin areas draining through the lymphatics of those regions bear to each other.

[7] Report of the Board of Health on a Second Outbreak of Plague at Sydney, 1902, by J Ashburton Thompson (W. A. Gullick, Government printer, Sydney, 1903).

[8] Report, Sydney, 1900, p. 42.

The proportion in which buboes are met with in the groin always preponderates over that in which the buboes occur in other regions of the body; this was very early observed among Eastern races who habitually go barefoot. Before long, however, the same preponderance was noticed among Europeans (though in small number) who did not go barefoot, but the hint thus given seems to have been overlooked and (perhaps in consequence) assumed infectiveness of ground surfaces became a prominent feature in writings on the etiology of plague. But at Sydney in 1900 I was able to show that in no less than 73 per cent. of the 283 cases which exhibited buboes the latter were found in the groin although all the patients referred to were white, clothed in European fashion, and invariably shod.[10] The validity of the banal explanation of the preponderance of buboes in the groin thus seemed to be rendered more than doubtful. But I had pointed out in the same report that the infection of plague was received by man, for the most part, within buildings, which seems also to have been noticed in India.[11] Now, if the infection be usually received by man in houses, &c., the objection raised above to the banal explanation of the preponderance of groin buboes must be revised, for there is a time of day when nearly all people, whites as well as others, go barefoot—namely, when they are going to bed or rising from it. At that time, therefore, infectious material deposited on floors, carpets, &c., by rats (or otherwise) would be more likely to come in contact with the unprotected skin of the feet than with that of any other part of the body. So that, although conjunction between a recent breach of the epithelium and deposited infection in the requisite state of activity cannot often happen, here is the opportunity for it at all events, and plague was not so frequently contracted by our people in either epidemic but that possibly those persons who exhibited groin buboes might have received the infection in that way. Let us try, then, to ascertain what the fact was. Does the record contain any cases in which infection resulting in groin buboes was probably not contracted by casual contact with deposited virus of the unprotected skin of the lower extremities? If it turn out that it does the hypothesis under examination will be very greatly weakened; it must, indeed, be discarded as an explanation of epidemic bubonic plague.

Among the 139 cases which constituted the epidemic there were 106 in which buboes occurred in the groin. But it is necessary to speak more exactly. Our present concern must be with primary buboes, since these alone indicate the region of skin through which the virus entered; and in order to leave no room for possible confusion between primary buboes and secondary glandular swellings it is desirable to take into account only those cases in which the groin bubo was solitary. Then the expression "groin bubo" is loose. A bubo in one of the oblique set of inguinal glands indicates infection through the skin of the lower part of the trunk. Buboes in one of the vertical set of femoral glands alone indicate infection through the skin of the feet or of other part of the lower extremity. An examination intended to discover whether there were buboes betokening infection through the skin of the lower extremity must be limited, therefore, to cases which exhibited *solitary* buboes in one or other gland of the *femoral* chain. The total number of such cases was 60, but the majority are not available for the present purpose. Thus the place at which the infection was taken could not be determined in 16 of them; either the inquiries made failed to reveal any clue to it or else the evidence for infection at home and at work seemed equally cogent. These 16 must be thrown out, therefore, for they (or some of them) may have been infected at their place of residence, where they were admittedly exposed to the risk ascribed to bare feet which is now under investigation. In 25 other cases it was considered that the patient did receive the infection at his place of residence, so that these too must be thrown out for the reason just given. In three others the place of employment probably was the place of infection but the details left room for some slight doubt; these are excluded by way of precaution. Three more were Chinese, concerning whom either information of the required kind could not be got at all or it was untrustworthy. Lastly, one was a woman whose movements could not be traced. So that 48 of the 60 have to be discarded. There remain 12 patients who had solitary femoral buboes and who are confidently adjudged to have received the infection away *from home and therefore while fully clothed. Of* these patients eight inhabited houses in neighbourhoods which were distant or even remote from the infected area and which were at all times free from suspicion of infection with plague (yielded neither indigenous cases nor plague rats); and while, on the one hand, 11 of the residences bore no traces whatever of infestation with rats (the twelfth alone having exhibited some slight signs), on the other hand, the places at which the patients were employed were badly infested and had yielded dead rats in number in ten instances at least. It is certain that these persons all fell into danger at their place of employment and apparent that they were not infected at home. At their employment they were fully clothed; their lower extremities were protected by boots, socks, and trousers, or (in one case) by stockings and petticoats, while their hands, arms, necks, faces, and in some cases, no doubt, their chests too were uncovered, exposed, and in no way protected from casual contact with deposited infection and therefore they should, *ex hypothesi*, have exhibited cervical or axillary buboes. In fact, however, they none of them did so. They were all of them inoculated in one or other lower extremity—in that very area of skin which beyond all doubt was well protected from casual contact with deposited infection. These 12 cases form but a small proportion of the 139 of which the second epidemic consisted, but the necessary rules under which they were selected, in circumstances where great caution was indispensable, led to rejection of several others which, were they to be cited as examples of a fact otherwise ascertained, might have been included. These 12 persons then were not infected by feeding for the reason drawn from the pathology of plague which has already been mentioned; it has just been shown that they could not have been inoculated in the lower extremity by casual contact with deposited infection and none of them had had any communication with preceding cases of plague. How, then, did they come to contract the disease? There is, in my opinion but one plausible—nay, but one possible—explanation. Inoculation in that situation and in those circumstances can have been brought about only by a suctorial parasite. On the whole the parasite which is best fitted to fulfil all the requirements of the case is the flea.

Several *a priori* objections have been raised during two or three years past to Simond's hypothesis of the flea[12] which, I may be permitted to add, I had myself accepted as a working hypothesis before I had had any practical experience with epidemic plague on the ground that it reconciled a much greater number of discrepant and even contradictory observations which had then been recorded than any other suggestion which had been made.[13] I conclude, therefore, by mentioning first that the indirect objections raised by Nuttall[14] on grounds furnished (*a*) by his unsuccessful experiments on the transmission of plague from animal to animal by means of bed bugs and (*b*) on the rapidity with which the bacilli of several diseases, among which plague was not included, lost their virulence after entering the stomach of the flea, have recently been met. Successful experiments on the transmission of plague from animal to animal by means of fleas have now been reported by Raymond and Gauthier working at Marseilles[15] and by Elkington working at Bombay,[16] both, be it remembered, thus confirming experimental results originally reported by Simond himself.[17] Secondly, that the objection raised by

Galli-Valerio,[18] with him Nuttall,[19] on insufficient grounds—namely, that "rat fleas" do not bite man—has also been met by direct experiments recorded by the observers just mentioned, as well as by Tidswell at Sydney. The species pulex fasciatus (Baker) and pulex pallidus will freely bite man and can even live on his blood alone for several weeks. I take this opportunity of pointing out that Tidswell[20] first observed pulex pallidus to be a species which most commonly infests the rats of the Australian coast line, an observation which was found to hold good with rats in India after he had communicated it to correspondents at Bombay.

The question which was asked above concerning inoculation by casual contact with deposited infection must now be put with reference to transmission of the infection by the flea. The former was there admitted to be a possibility which sometimes, in all likelihood, had been realised; but the chances against conjunction of the necessary circumstances are so many that it cannot be regarded as the cause of epidemics. The latter, also, appears to be a possibility; but does it take practical effect often enough to constitute that cause of epidemics which otherwise is still unrevealed? The answer cannot be drawn from laboratory experiments; it can be furnished only by epidemiological investigation and the evidence must always remain indirect. Much to the purpose has been recorded in my report on the epidemic of 1902.[21] We are of opinion that the hypothesis of the flea fully explains its observed course but the evidence is too lengthy for inclusion in the present communication.

Nulla autem est alia pro certo noscendi via, nisi quamplurimas et morborum et dissectionum historias, tum aliorum tum proprias collectas habere, et inter se comparare.—MORGAGNI *De Sed. et Caus. Morb.*, lib. iv., Proœmium.

ROYAL SOUTHERN HOSPITAL, LIVERPOOL.

FIVE CONSECUTIVE CASES OF INTESTINAL OBSTRUCTION SUCCESSFULLY TREATED BY OPERATION.

(Under the care of Mr. G. P. NEWBOLT.)

CASE 1. *Intestinal obstruction produced by a large gall-stone.*—A married woman, aged 54 years, was admitted to the Royal Southern Hospital, Liverpool, on August 4th, 1902, suffering from intestinal obstruction. She was a big, stout woman, weighing 18 stones and measuring 44 inches round the waist and was the mother of nine children, the youngest being aged 12 years. Her bowels were moved naturally eight days before admission and again two days later after an aperient. No flatus had passed for six days but an injection had brought away fæcal matter. She had been vomiting brown, foul-smelling fluid for a week past, her tongue was dry, her pulse was 92, and her respirations were 28. The onset of the attack was sudden and the pain spread all over the abdomen. She had had similar, only slighter, attacks previously but had never been jaundiced and had never had pain in the region of the gall-bladder. Examination per rectum revealed nothing. The abdomen was somewhat distended but there was very little tenderness and the walls moved freely with respiration. When seen at 10.30 A.M. shortly after admission there was no vomit for examination and it was decided to wait for a while in order to get a specimen of the vomit before opening the abdomen. This was done as although there was some distension yet the woman did not seem to be in the distress which is usual when intestine is nipped or tied down. Her obesity did not invite laparotomy unless absolutely necessary. The trouble had lasted a week and she admitted having had similar attacks which she had got over. However, some hours later she had an attack of fæcal vomiting and there was no object in further delay. At 8 30 P.M., the patient being under chloroform, Mr. G. P. Newbolt opened the abdomen in the middle line with a four-inch incision, its centre being at the umbilicus. Some coils of distended small intestine escaped and on passing the hand into the abdomen a hard lump was at once felt in the intestine occupying the left iliac fossa. On drawing it up to the surface a large gall-stone was found to be blocking the gut. All the intestines were now returned except the portion containing the stone, and the abdomen having been shut off with sponges the intestine was tightly held on each side of the stone whilst the latter was removed through a longitudinal incision in the gut. The stone was squeezed out and the incision was closed by two layers of interrupted suture, one taking the edges of the wound and the other (a Lembert suture) prolonged well over each end of the incision. The abdomen was closed with through-and through silkworm-gut sutures and the patient left the table with a pulse of 108 which soon fell to 92. She was kept under opium. Flatus was passed on the second day and she made a perfect recovery, leaving the hospital five weeks after the operation. The stone was egg-shaped, one end being fractured, and this lay uppermost or nearest the duodenum. It measured two inches in length, one and a half inches in diameter, and three and a half inches in circumference; it weighed 303 grains when dry. Around the broken end was a ring of dark pigment which looked as if this portion of the stone had been gripped by encircling mucous membrane and stained. The fracture was apparently a recent one. Mr. Newbolt saw the patient on June 5th last and she was perfectly well.

CASE 2. *Intestinal obstruction produced by a band.*—The patient, a single woman, aged 31 years, was first seen by Mr. Newbolt in consultation with Dr. W. Murray Cairns on July 16th, 1902 Her previous history was good: she had never had any digestive trouble but had had scarlet fever six months before and on examination a mitral murmur was present. On July 14th, two days before Mr. Newbolt saw her, she ate an ordinary midday meal of beef, &c., and one and a half hours later she was seized with acute pain in the umbilical region which doubled her up on account of its severity and made her vomit Her bowels acted twice after the pain began, the second motion being attended with a good deal of griping. She was not collapsed; her pulse was 60, her temperature was normal, and her illness simulated an attack of colic. Mustard poultices were applied to the abdomen. On the next day she was no better; there were constant pain, vomiting, and no passage of flatus. Dr. Barr saw her at this stage of her illness and diagnosed obstruction by band. On July 16th, when Mr. Newbolt was called in with a view of operative proceedings, the patient was still vomiting, no flatus had been passed, and slight distension of the abdomen appeared; the vomit was becoming feculent and the pain was constant. On examination her pulse was 70 and her temperature was normal; her face was of a good colour; the urine was scanty; the abdomen was not moving with respiration and was tender all over with a marked tympanitic area. Mr. Newbolt had her removed in an ambulance to the Royal Southern Hospital. Here he opened the abdomen in the middle line by an incision four inches long with the umbilicus at its centre Distended small intestine at once presented and was allowed to escape. Contracted gut appeared in the left iliac region and tracing it back Mr. Newbolt came upon the seat of the obstruction which was low down in the ileum. A thin white fibrous band exactly like a vocal cord was attached at one end to the mesentery; it encircled the gut and was again attached to the mesentery on the opposite side. It was a separate structure and not a thickening of the peritoneal coat; there was no trace of old peritonitis and the band looked as if it might be of congenital origin. It was cut away close to its origin and insertion. The abdominal wall was closed in layers and the patient was given a saline injection per rectum. Flatus was passed on the third day and the patient made a good recovery. During convalescence she had an acute urticarial rash all over the body followed by some bronchitis. She went home five weeks after the operation. Her further history, for which Mr. Newbolt is indebted to her brother-in-law, is interesting. In September, 1902, she went to Palestine and did well till early in November when whilst at a hotel in Damascus a recurrence of the symptoms of obstruction suddenly supervened. She was taken to the Scotch Mission Hopital in that town and was there operated upon by the surgeon in charge. A firm fibrous band was again found in the lower portion of the ileum and was divided with complete relief to the symptoms. She again made a good recovery.

CASE 3. *Intestinal obstruction produced by an omental band in a patient twice operated upon for strangulated umbilical hernia.*—A married woman, aged 60 years, was admitted to the Royal Southern Hospital on July 8th, 1902, suffering from symptoms of intestinal obstruction. 12 years previously she had been operated upon for strangulated umbilical hernia by a Liverpool surgeon and on Sept 4th, 1901 (ten months before), Mr. Newbolt had operated upon her for a recurrence of this condition. She then had a huge umbilical hernia which took one and a half hours to unravel, but though at her first operation she was told that she would never survive a second, yet she made an unimpeded recovery. When called to see her by Mr. M. J. Campbell on the occasion of her third attack she told Mr. Newbolt that 48 hours previously after lifting a heavy weight she had been seized with sudden pain in the left iliac region, that vomiting at once set in, and that she had passed no flatus since. On examination she did not look very ill, her pulse was 80, and her temperature was normal. No vomiting had taken place. Knowing, however, her previous history Mr. Newbolt persuaded her to go into hospital as soon as possible. It might be stated that she was under the influence of opium. An enema brought away some scybala and it was thought that some flatus was passed; the ward sister, a woman of much experience, was so certain of this that Mr. Newbolt decided to wait for further symptoms. She vomited some bile-stained fluid once in the afternoon and once the night that she was admitted, and as the effect of the opium passed off she complained of pain at the umbilicus. Very little urine was passed and the treatment practically was starvation. On the next day (the 9th) there were no change in her condition and no obvious distension, though she was a very stout woman. With a view, therefore, of eliciting symptoms she was given one grain of calomel. Within an hour this was followed by violent fæcal vomiting. Operation was at once proceeded with and the abdomen was opened through the old hernial scar. Coils of matted intestine presented themselves and were separated one from another, but after doing this for half an hour Mr. Newbolt came to the conclusion that the intestine he was dealing with did not account for the trouble. On searching the left iliac region he came upon some coils of distended intestine and on tracing them downwards found a thick omental band which was binding the small intestines down and causing the obstruction. Mr. Newbolt thought that the band was a piece of omentum tied at a previous operation which had become attached to the posterior wall of the abdomen and under which a knuckle of gut had slipped. On dividing the band and ligaturing and removing the ends the bowel was at once released. The wound in the abdominal wall was closed with silk sutures and the patient was put back to bed. As before she made an uninterrupted recovery, her pulse never rising above 96, and when seen in July of this year she remained well.

CASE 4. *Acute appendicitis complicated by intestinal obstruction.*—The patient, a married woman, aged 37 years, was sent to Mr. Newbolt by Mr. S. Kellett Smith and was admitted to the Royal Southern Hospital on April 7th, 1903, suffering from symptoms of intestinal obstruction. On April 3rd the patient was taken ill with a severe bilious attack and her bowels acted on the following day. After this no flatus was passed and she was sick occasionally. Pain started in the left iliac region and gradually spread all over the abdomen. She had taken a purgative without effect and an enema brought away scybala. Though married for some years she had had no children; menstruation was regular and there was no history of any uterine trouble. On admission the patient, a well-nourished and healthy-looking woman, presented the following symptoms. The pulse was 100, the temperature was 101·4° F., the abdomen was tender all over and distended, and the tongue was dry. Nothing could be made out per rectum or per vaginam. Liver dulness was somewhat obscured by distended intestine. The patient being under chloroform, her abdomen was opened in the middle line when a good deal of peritonitic fluid escaped and distended intestines were seen. An examination showed that the intestines were bound down in the pelvis and so the Trendelenburg position was adopted. On enlarging the incision downwards it was evident that there was inflammatory mischief in the cæcal region and on attempting to free adhesions a large abscess was opened; sponges were packed in and the Trendelenburg position was at once abandoned. An incision was now made over the appendix and an abscess was opened deep in the pelvis on the right side. After some trouble the appendix, which had perforated at its base, was removed together with a stercolith which lay in the abscess cavity. This cavity, which was lined with a [illegible] ugh [illegible] ing [illegible] tes- [illegible] ary [illegible] by an omental band. After freeing this flatus at once was passed. Some four or five pieces of omentum which were adherent to the pelvis were removed, the parts were thoroughly sponged out, and the wound was closed, a glass tube being left above the pubes. Two hours after operation three grains of calomel were administered and the bowels acted freely through the night. On the next morning the distension was less, the pulse was 84, and the temperature was normal. The tube was removed from the vagina on the second day and a gauze drain was left in two days longer when on syringing through the iliac wound there was a free drain through the vagina. There was free discharge from both abdominal drains and some sloughs separated but the rest of the incisions healed well. The patient made a slow but good recovery, her chief trouble being intense pain in the bladder and frequency of micturition, though her urine was quite normal. These symptoms abated as the median drain track closed and no doubt were due to some inflammatory trouble involving the bladder wall. A cross examination elicited the fact (unobtainable before the operation) that she had had attacks of "cold in the stomach" on one or two occasions previously.

CASE 5. *Intussusception of the ileo-cæcal variety.*—The patient, a female child, aged nine months, was taken ill suddenly on the afternoon of May 21st, 1903, with pain in the stomach and vomiting. She was sent into hospital by Dr. W. G. Williams for operation. When Mr. Newbolt saw her 24 hours after the onset of the attack she was somewhat collapsed and had passed no motion since being taken ill, but there were blood and mucus on the diaper. Nothing definite could be felt through the abdominal wall, but on examination per rectum the finger passed up as far as possible together with pressure on the abdominal wall from above was just able to touch the apex of an intussusception. The child did not resist examination, being too collapsed. The pulse was 128 and the respirations were 28. On opening the abdomen in the middle line by a two-inch incision with the umbilicus at its centre an intussusception was at once seen and Mr Newbolt was able to reduce the greater part of it from within the abdomen, but the last portion had to be brought outside and was reduced with difficulty, a portion of the ileum near the valve being much thickened and congested. The abdomen was rapidly closed with silkworm gut. The child was very ill for 48 hours; she was put to the breast soon after the operation and the bowels were moved in 36 hours. Recovery was uninterrupted and she is now in good condition.

Remarks by MR. NEWBOLT.—An interesting point in Case 1 was the fact that although the patient had been vomiting fæcal matter for at least 24 hours before the operation, and this I afterwards learned was undoubtedly so, yet she had not the distressed appearance which is usually associated with this condition. The stone was no doubt passed by ulceration from the gall-bladder into the duodenum and two cases which I have recently seen substantiate this view. In one the gall-bladder was adherent to the colon and full of pus which would but for surgical interference have opened into that viscus. In the other the gall-bladder, full of stones, was adherent to the duodenum and the stones would doubtlessly have ulcerated through had circumstances allowed them to do so. In one of the cases quoted by Barnard in his paper in the *Annals of Surgery* for August, 1902, the stone could be passed post mortem back along the duodenum through the aperture into the gall bladder whence it started. The idea that big stones passed through the dilated ducts is evidently fallacious. In my case I passed my hand up to the liver in order to feel for other stones, but I failed to discover anything abnormal and the patient's condition did not justify any prolongation of the operation.

In Case 2 the occurrence of a second obstruction of the same nature as that which necessitated the first operation is interesting; moreover, it shows the value of a guarded prognosis in these cases. In Case 3 the fact that the patient underwent two severe but successful operations for strangulated umbilical hernia and one for obstruction by a band says much for the vitality of an unpromising looking patient with a very feeble pulse. The administration of calomel with a view of eliciting symptoms was, I think, justifiable on account of the difficulty in coming to a definite diagnosis and the feeling one had that an obstruction existed. Of course, everything was in readiness for immediate operation. Case 4 emphasises the value of early operation in cases of appendicitis whereby complications such as were met with in this case may be avoided. I am of opinion that had I opened the appendicular abscess from the right side in this case a second operation would have been necessary in order to relieve the obstruction caused by a binding down of the large intestine by inflammatory trouble, no doubt secondary to the appendicitis. I may add that on those few occasions on which I have been tempted to deviate from the rule of opening the abdomen in the middle line in cases of obstruction I have always regretted it. In Case 5—the intussusception—the more one sees of these cases the more one feels inclined to operate at once and not to waste time in employing other and less trustworthy methods of reduction.

BURY DISPENSARY HOSPITAL.

A CASE OF TRAUMATIC TETANUS; RECOVERY.

(Under the care of Dr. J. W. COOK.)

FOR the notes of the case we are indebted to Dr. A. G. Wilson, late senior house surgeon.

A youth, aged 19 years, a labourer, was admitted into Bury Dispensary Hospital on July 2nd, 1902, suffering from a severe crush of the right great toe. The injury had been caused by the fall of a piece of timber. Amputation was not considered unavoidable; the toe was dressed with boric lint soaked in boric lotion, the dressing being changed every four hours. On the third day after admission a slight blush was observable extending about half an inch from the wound; the latter was commencing to discharge a large quantity of pus. His temperature was 99 4° F. The dressing was changed to lint soaked in creolin solution of the usual strength and changed every four hours. During the next few days a portion of the toe sloughed and the wound discharged very foul pus. The evening temperature was usually 99·2° and the morning temperature was normal. The wound gradually became cleaner and on the tenth day after admission the dressing was changed to iodoform gauze. The patient was apparently progressing favourably but on the morning of the sixteenth day after admission (July 18th) he woke up complaining of slight stiffness of the neck and difficulty of opening the mouth. On examination the muscles of the neck were not abnormally hard and the mouth could be opened to almost its usual extent but risus sardonicus was present to a very considerable degree, the lips being drawn back, exposing the teeth, and the corners of the mouth being depressed. His temperature was normal. The patient, although he was in a state of intense fear at the idea of having lockjaw, grew no worse during the day. The wound which looked healthy was well rubbed with solid silver nitrate. On July 19th the patient had had a good night but on waking complained of severe pain in the back of the neck. He could open his jaws to the same extent as on the previous day. He complained of difficulty in swallowing and refused all but liquid food. One drachm of solution of hydrochlorate of morphia was given His diet consisted chiefly of milk and eggs beaten up in milk. The temperature in the mouth was normal. There was no albumin in the urine. On the 20th the patient's condition was identical with that of the day before. His temperature was normal and there was no albumin. One drachm of solution of hydrochlorate of morphia was given to relieve the pain. On the 21st the muscles of the neck felt hard. There were no spasms. The temperature and pulse both morning and evening were normal. The patient had very little pain and was not at all exhausted but was very restless and continually wanted to be propped up in bed. On the 22nd the neck and masseter muscles felt like wood. The head was somewhat retracted and the patient complained of pain in the back. He had a few very mild spasms arching his back and neck during the day. His temperature was 99·4°. He took bread and milk and eggs and milk. On the 23rd the neck, back, and abdominal muscles were very rigid and hard. The temperature was 99·8°. The muscles of the jaw were rather better, those of the legs, arms, and hands being quite unaffected. The patient had not much pain. There were no spasms. Three drachms of syrup of chloral were given during the day and 20 cubic centimetres of Pasteur's antitetanic serum were injected. On the 24th the muscles of the neck and back were still rigid; the abdominal muscles were rather better. The tongue was foul. The pulse was 90 and the temperature was 99 6°. Four drachms of syrup of chloral were given during the day. On the 25th the muscles of the neck and back were unchanged and the abdominal muscles were more rigid. His temperature was 99·8°. Three drachms of syrup of chloral and 20 cubic centimetres of antitetanic serum were administered during the day. On the 26th the muscles of the thigh were rather rigid; there was much pain in the back of the neck. Ten cubic centimetres of serum were injected. There were no spasms. On the 27th the legs, back, and abdomen were much better. There was less pain. Ten cubic centimetres of serum were injected. On the 28th there was decided improvement. Ten cubic centimetres of antitetanic serum were injected. On the 29th the patient was better. There was no pain. Ten cubic centimetres of serum were injected. By August 2nd the patient was quite free from all muscular stiffness and was discharged on August 16th with the toe practically healed.

Remarks by Dr. WILSON.—The above case of traumatic tetanus may be found interesting owing to the mild character of the onset of the disease and to the long time which elapsed before the affection was at all severe. The following points in the case are of interest. The incubation period was above the average, as is usual in cases which recover. During the period of four days from the morning of the 18th to the evening of the 21st the patient did not get any worse. His temperature was never above normal and he slept well. During this period the risus sardonicus was extremely well marked. The patient was of a very neurotic type. Illustrating this on two occasions before the onset of the tetanus he complained of sleeplessness at night. He was given one drachm of water in a minim glass which he thought was solution of hydrochlorate of morphia. He not only slept all through the night but complained of excessive drowsiness all through the next day. This fact, together with the non-progress of the disease from the 18th to the 21st and the knowledge that immediately he complained of stiff neck the other patients told him he had lockjaw, suggested the possibility of his simulating the disease. On the morning of the 22nd, however, the true nature of the affection was unmistakeable. No local treatment beyond the one cauterisation with silver nitrate was undertaken. The injections of serum seemed undoubtedly to relieve the tension of the muscles as when they were stopped for one day he had a slight relapse. It is probable, however, that he would have recovered without them as he never seemed at all exhausted.

Medical Societies.

MEDICAL SOCIETY OF LONDON.

Annual General Meeting.—Presidential Address.—Adaptation and Compensation.

THE annual general meeting of this society was held on Oct. 12th, Mr. A. PEARCE GOULD, the President, being in the chair. The annual report was taken as read. The treasurer's report and balance-sheet were presented and adopted, it being pointed out that unusual expenditure had been incurred owing to the necessity which had arisen for legal proceedings in the enforcement of the terms of the lease of the premises occupied by the society. Votes of thanks to the retiring officers were proposed and adopted and the incoming President, Dr. F. DE HAVILLAND HALL, then took the chair.

At the ordinary meeting which followed Dr. de Havilland Hall delivered his presidential address, taking as his subject a brief retrospect of certain of the papers relating to diseases of the circulatory and respiratory systems which had been read before the society in the last 25 years. He directed attention to the two discussions on intrathoracic aneurysm, one having been introduced by Sir R Douglas Powell in

December, 1889, and the other by himself in 1900. Besides these there had been numerous other papers on the same subject. The earliest communication within the period referred to was a paper read by Dr. T. Gilbart Smith in November, 1878, which illustrated the extreme difficulty of diagnosing cases of aneurysm with pressure upon the root of the lung, especially if there were pleural effusion in addition. The possibility [illegible] borne in mind in all [illegible] President commented upon the absence of any definite statement as to the position of the left vocal cord in cases of intrathoracic aneurysm. He had almost always found it fixed in the cadaveric position, whereas the late Dr. W. M. Ord had usually found the vocal cord fixed in the position of abduction. This was a point which might certainly be cleared up without much difficulty. In most of the papers the action of iodide of potassium was commented on. Sir Benjamin Ward Richardson could see "no physiological reason for its value." Remarkable diversity of opinion existed on the subject. Was there any more general consensus now, 18 years after the discussion, and was not this a question which required to be settled? One thing iodide of potassium certainly did, it relieved pain. As early as March, 1881, the attention of the society was directed to the subject of malignant endocarditis. The mode of entrance of the germs producing the disease was discussed as well as its nomenclature. Dr. Sidney Coupland suggested "septic" [illegible] name for the disease. In a p[illegible] Coupland commented on the [illegible] malignant character was graft[illegible] changes in the valves. In one of the cases recorded recovery followed after the administration of sulpho-carbolate of sodium. The President expressed a hope that in the discussion which was to take place on the use of serum and other inoculations in pyogenic infections some reference would be made to the treatment of malignant endocarditis. In commenting on a case of relapsing or intermittent pneumonia communicated by the late Sir Andrew Clark in 1884 the President drew attention to the statement that in about one third of his hospital patients there was absence of cough and expectoration and he remarked that pneumonia occurring in gouty subjects was particularly liable to be so characterised. The President agreed with the caution which Sir Andrew Clark expressed as to the necessity of not overloading the system by too much nourishment, and also with the view that on the whole stimulants did more harm than good. The important subject of venesection in pneumonia was raised by Dr. F. Lucas Benham, and the cases he quoted were most convincing as to the good effect of this method of treatment in certain cases of pneumonia. The diseases of the pleura had been the subject of numerous and valuable papers. The first in the period under consideration was in 1880 by Sir William H. Broadbent who pointed out how the physical signs were modified when the lung was large and consolidated and deeply immersed in the fluid. Two most important discussions had taken place upon empyema and its treatment. The first was based upon a paper by Dr. Thomas Churton of Leeds. He divided cases of empyema into three sets or species—(1) those on the outer aspect of the lung; (2) those at the base between the lung and the diaphragm; and (3) those on the inner aspect between the lung and the spine and the mediastina. It was from a failure to recognise the varied situations of an empyema that mistakes in diagnosis occasionally arose, but the diagnosis of a small empyema between the lobes of the lung was a mattter of the greatest difficulty. The discussion upon the treatment resolved itself mainly into whether simple incision or resection of a portion of one or more ribs should be practised and the President expressed himself in favour of the latter. The two most weighty communications on pneumothorax and pyopneumothorax had been made by Dr. Samuel West which had led the President to modify the view which he formerly held as to the undesirability of interfering with pyopneumothorax due to pulmonary tuberculosis and he alluded to a case recently under his care to prove that even advanced disease of the lung was no necessary contra-indication to incision and drainage of the pleural cavity should pyopneumothorax be present.

Dr. G. A. **GIBSON** (Edinburgh) read a paper entitled "Adaptation and Compensation," illustrated by lantern slides. The anatomical changes in acromegaly, arterial hypermyotrophy, arterio-sclerosis, cardiac degeneration, and other degenerative changes were brought forward and described in illustration of the processes of adaptation and compensation. (This paper will shortly appear in our columns.)—Dr. J. **MITCHELL BRUCE** remarked on the application of these same processes in therapeutics.—Dr. A. G. **AULD** recalled many observations by the late Professor Coats of Glasgow showing that sclerotic changes in the arteries depended on deficient nutrition.—Dr. **GIBSON** replied.

CLINICAL SOCIETY OF LONDON.

Erosive Gastric Ulceration successfully treated by Operation.—Cases of Acute Hæmorrhagic Pancreatitis.

A MEETING of this society was held on Oct. 8th, Dr. **FREDERICK TAYLOR**, the President, being in the chair.

Sir **DYCE DUCKWORTH** and Mr. **H. T. BUTLIN** communicated a paper on a case of Erosive Gastric Ulceration with Severe Hæmatemesis; Operation; Recovery. The patient was a woman, aged 29 years, who was admitted into St. Bartholomew's Hospital on Nov. 21st, 1902. There was a history of three weeks' pain after food but no vomiting or hæmatemesis until the day before admission. The bleeding continued to recur in spite of adrenalin chloride, rectal feeding, and other measures. On Dec. 4th Mr. Butlin took over the care of the patient and with the assistance of Mr. O. B. Lockwood opened the abdomen and made an incision in the anterior wall in the long axis of the stomach. Nothing that could be called an ulcer was found on examining the interior of the organ, but in the greater curvature near the pylorus the mucous membrane over several square inches was pink and markedly different from the rest of the membrane which was of an ivory yellow tinge. At various points on this pink area were found slight excoriations, fissures, and tiny points from which blood slowly oozed. Nine of these points were ligatured with a purse-string suture of fine silk thread and the opening in the stomach was closed by a continuous silk suture which embraced all three coats. The abdominal wall was closed by three layers of continuous silk sutures the ends of which were left out at each end of the wound. The operation lasted three-quarters of an hour and was well borne, not more than a drachm of blood being lost. Some vomiting followed the operation. On Dec. 5th the temperature fell from 101° to 99° F. Three ounces of acid green fluid were vomited but no blood. Feeding was carried on by the bowel, while saline solution, one pint, with a drachm of liquor calcis saccharatus in it, was also administered by the rectum. By Jan. 9th the patient was taking boiled fish and on the 14th minced meat. By Feb. 4th she was well and was sent to the Convalescent Home at Swanley. The case afforded confirmation of the observations of other investigators on the occurrence of oozing of blood from several small points at once as distinct from ulceration. The condition of the gastric mucous surface discovered in this case was probably the starting point of most, if not of all, gastric ulcers and it seemed probable that if the hæmorrhages dependent on it proved fatal in any instance the actual lesions would not be detectable after death.—Mr. C. W. **MANSELL MOULLIN** recalled the paper which he had read before the Clinical Society three years ago on this subject and which was published in THE LANCET.[1] He had operated in 11 cases of erosive ulcer and he discussed the differences in the appearances of the mucous membrane during life and after death. He urged that operation in these cases should be undertaken before the patient had become too exhausted. It had been stated that hæmatemesis was only fatal in 3 per cent. of the cases of gastric ulceration but he pointed out that no one had ever proposed to operate in every case of gastric ulcer. Only about 10 per cent. of the cases were really serious and these only concerned the surgeon. The indication for operation was the occurrence of a succession of severe hæmorrhages, especially if associated with intense anæmia and if medical measures had failed.—Dr. F. **DE HAVILLAND HALL** agreed as to the indications for operation but demurred to the statement that 10 per cent. of the cases were serious, adding that in nine years at the Westminster Hospital, although he had seen many cases of gastric ulcer, not one of them had proved fatal and in only one instance had operation been performed. While admitting the occasional need for operation he believed it was only rarely called for.—Mr. **ARTHUR E. BARKER** advocated the operation of gastro-duodenostomy which not only tended to bring about cessation of the bleeding but also gave the stomach rest and enabled it to empty its contents.—Mr. F. C. **WALLIS** commented on the difficulty of making out the situation of the ulcer from external examination of the stomach and he advocated making an incision into the organ for that purpose.—Dr. **WILLIAM PASTEUR** discussed the differential diagnosis of hæmatemesis from gastric erosion and that due to gastric ulceration. In the former the hæmorrhage was, he believed, constantly recurring.—Mr. C. R. B. **KEETLEY** observed that the practice of operating to find the bleeding spot might be all very well when every possible facility was available but it was hardly practicable in every case. In a severe case of his own he experienced considerable difficulty in locating the bleeding spot, although he had opened the stomach pretty freely. He ultimately found that the ulcer was adherent to the diaphragm. He separated the adhesions and packed the cavity and the patient recovered, though she subsequently had to undergo gastro-enterostomy, an operation which he held in great esteem. He referred to a paper by Mr. Willonghby Furner.[2]—Mr. **BUTLIN**, in reply, remarked on the enormous hæmorrhages which might occur from tiny bleeding points in the stomach, just as they could in similar circumstances from the nose. While admitting the difficulty of discovering these points he thought it better, speaking as a surgeon, to attack these bleeding spots directly whenever that was possible. If they could not be located gastro-enterostomy might be performed but even this did not always check the hæmorrhage.—Sir **DYCE DUCKWORTH**, in reply, emphasised the necessity of recognising the type of case in which operation was called for—namely, that in which sudden profuse and successive hæmorrhages occurred. This was a character which he believed attached to erosions as distinct from simple ulcer of the stomach. Other differential features were the suddenness of the onset without much previous history and without pyrosis. Discussing the etiological factors, he remarked on the frequent association of gastric ulcer with intense anæmia and with the wearing of tight corsets.

---

[1] THE LANCET, Oct. 20th, 1900, p. 1125.

Mr. **ANTHONY A. BOWLBY**, C.M.G., communicated a case of Acute Hæmorrhagic Pancreatitis. The patient was a man, aged 41 years, who was seized with severe abdominal pain and vomiting on Nov. 19th, 1902. During the next two days there was some complaint of flatulence and constipation and the vomiting continued. The abdomen was tender but no swelling could be felt. The bowels acted well after enemata. On the third day of the illness the patient became delirious and from that time onwards suffered from delusions. The urine was very greatly diminished in quantity. On the fifth day after the illness commenced there was a sudden attack of pain with severe vomiting, followed by great and rapid distension of the abdomen and complete obstruction. For the relief of this his abdomen was opened and there was found to be some general early peritonitis with old adhesions but no mechanical obstruction of the bowel. A coil of the small intestine was opened to relieve the distension but failed to save the patient's life. The post-mortem examination showed a very large hæmorrhage surrounding the pancreas and extending down to the pelvic region. The pancreas also was engorged with blood and there was general peritonitis.

The **PRESIDENT** also made a communication on a case of Acute Pancreatitis. The patient, aged 68 years, was admitted into Guy's Hospital on Feb. 3rd, 1899. At a public-house he had ordered some rum and had filled up his glass from a bottle supposed to contain water and had drunk the whole. This bottle was afterwards said to contain oxalic acid of unknown strength. Emetics were given and he vomited freely. Though not apparently much affected at first he afterwards became collapsed, tremulous, and cyanosed, but recovered towards the evening. On admission the mouth and lips were slightly excoriated. He was suffering from emphysema and slight bronchitis. On the following day he appeared to be well and left at his own urgent request. He went home by train a distance of five or six miles, arriving very feeble and ill, and two days later he returned to the hospital. He was then cyanosed, feeble, with rapid pulse and breathing. There was now no soreness of the mouth or epigastric pain or pain on swallowing. His bronchitis was worse and this became the prominent feature, with increasing feebleness of the pulse, until his death on the 23rd. Post mortem there was emphysema of the lungs, with purulent bronchitis and pleurisy. Ten ounces of blood were found in the substance of the great omentum and the pancreas presented a condition of interstitial hæmorrhagic pancreatitis, was enlarged, hard, and infiltrated with blood. There was neither peritonitis nor fat necrosis. The kidneys were slightly granular. The President discussed the relation of the condition of the pancreas to that of the chest and to the ingestion of the oxalic acid. The entire latency of the pancreatic lesion was pointed out as the two other conditions combined to mask the symptoms which might have been attached to it.—Mr. **BARKER** remarked on the copiousness of the vomiting in these cases and asked if this had been noted by Mr. Bowlby and the President.—Mr. L. A. **BIDWELL** referred to a case in which he had operated last year. He had at first diagnosed pus in the gall-bladder but at the operation the gall-bladder and ducts were found to be healthy and in pursuing his exploration he let out a quantity of fluid from a cyst, after which the patient recovered. He had heard, however, that the patient had subsequently died and he supposed that a fresh collection had formed.—Mr. **BOWLBY**, in reply, said that the vomited matter in his case was very copious considering how little fluid the patient took.

SOCIETY FOR THE STUDY OF INEBRIETY.—A meeting of this society was held on Oct. 13th at the rooms of the Medical Society of London, Dr. Harry Campbell, the President, being in the chair.—Sir William J. Collins delivered an address entitled "The Institutional Treatment of Inebriety." He said that he approached the question rather from an administrative than a therapeutic standpoint. As first chairman of the London County Council Inebriates Acts Committee he had taken part in founding the certified reformatory at Farmfield, Horley, and as a visitor of Aylesbury Gaol he had watched the establishment and working of the State Inebriate Reformatory for women recently opened there. The Inebriates Act of 1898 had initiated an entirely new method in the treatment of the habitual offender and opened up new possibilities in their whole penological system. Some had regarded the process of amelioration of the lot of the sinner and the sot as having gone too far and denounced with Spartan rigour the softness of this degenerate dispensation. In administrative matters softness of heart was an insufficient compensation for the lack of hardness of head. In view of the difficulties encountered in housing even the industrious working classes in their large towns at rents alike payable and paying, he confessed he sometimes felt that in some directions they were in danger of making the way of the transgressor too soft. Having said this, he fully indorsed the view that in regard to the inebriate it was right to make the experiment—for as an experiment he looked upon it—of seeing what could be done under the optional powers given to county and borough councils by the Act of 1898. The old miserable round of repeated short sentences had proved a sorry and revolting farce as a means of reclamation. The prison, the asylum, the hospital, and the reformatory had all their uses in their social betterment, but up to the present the sorting of their contents had sometimes been somewhat perfunctorily performed. The greatest discrimination was required in so-called "borderland" cases in order to decide how to classify and how to treat the particular individual. Questions of moral responsibility were raised which required the thoughtful consideration alike of the philosopher, the physician, and the jurist, and the practical coöperation both of the large-hearted philanthropist and the common-sense scientist. They were in danger of the official and the commonplace so scornfully denounced by Charles Reade in that splendid contribution to solid fiction, "It's Never Too Late to Mend." Inebriety was called a disease, but it was a *disease of the will.* As with the hysteric, the inebriate said, "I cannot"; it looked like "I will not"; it was "I cannot will." Its successful treatment involved the problem of how to rehabilitate a human will. To restore the physical norm was the first essential but it was only the beginning of treatment. Alcohol in any form should be absolutely and at once withdrawn, both as drink and drug. It was on the moral plane they must work if they were to reconstruct character and not merely regulate conduct. Hedonism and necessitarianism would prove false guides and uninspiring mentors in the task of individual reclamation and social regeneration, even though they pursued the paths of despotic philanthropy so much in vogue in certain circles. Appeal must be made to higher sanctions than those of pleasure or even prudence. Frank recognition must be conceded to a conscious partnership of each individuality in the architecture

---

of his or her own character Means which did not appeal to a will free to choose, a will actuated by ideals which transcend natural and merely physical sanctions, might suffice to mould an automaton but would not restore a character To this end all treatment should be directed Removal from old associations, from town life back to nature, to work in the field or on the farm—work that grows and progresses under the hand by preference, exciting interest and perseverance towards an end in view Habits of industry and fixity of purpose were thereby inculcated Voluntary coöperation must be enlisted
on the personal influence of
to the world it was of the
help and supervision were
secured The work demanded tact and patience and the highest qualities of head and heart A social experiment it was, but one which, in view of their national vice, deserved to be well and truly tried

FORFARSHIRE MEDICAL A
of this society was held in the
on Oct 2nd, Professor A M St
Mr D M Greig read notes of a case of Gunshot Wound in the Chest in which a Mauser rifle bullet had traversed the right chest and at its exit had fractured the tenth rib As a sequel to this the tenth intercostal nerve had been caught and compressed by the cicatrix This was followed by the onset of an unusual spasm of the respiratory and of the extra respiratory muscles Excision of the fractured rib and resection of the nerve had been followed by immediate and permanent relief from the symptoms —Dr A McGillivray read a paper on the Use of Protargol in Ophthalmic Practice He considered that protargol was one of the most valuable therapeutic agents at present available in the treatment of certain conjunctival affections It possessed obvious advantages over nitrate of silver, for it was not precipitated by the chloride of sodium of the tears and it did not really coagulate the albumin of the tissues A 1 per cent solution dropped freely into the eyes thrice daily in catarrhal conjunctivitis gave better results than any remedy he knew of In certain forms of epiphora it might be combined with a solution of chloride of adrenalin of a strength of 1 in 10 000 In purulent conjunctivitis of the newly born he obtained excellent results by the use of a 10 per cent solution of protargol freely dropped into the eyes after the removal of all discharges by copious flushing with tepid normal saline solution —Mr Greig said that a weak solution of protargol was a most valuable remedy for the treatment of specific urethritis —Dr J Orr said that he had used 15 and 20 per cent solutions which had caused severe pain Now he was accustomed to use from 2 to 5 per cent solutions and had heard no complaints of their painfulness —Mr G Halley read short notes of ten cases of Strangulated Hernia He mentioned that though the number of the cases was small they were representative of sufficient varieties to be of interest The oldest patient was 80 years of age and the youngest was five months In only one case was the bowel gangrenous This was resected and an end to end anastomosis was performed The patient, however, succumbed on the next day One other patient died seven days after the operation In this case the bowel was healthy and was returned but the patient's condition was not good

BRITISH GYNÆCOLOGICAL SOCIETY —A meeting of this society was held on Oct 8th, Dr Heywood Smith, the President being in the chair —The President showed the following specimens, reading notes of the cases 1 A large Fibroid Tumour in Calcareous Degeneration removed from a sterile married woman still menstruating though 50 years of age The ovaries were cystic and were first removed, an elongated pedicle attaching the tumour to the fundus was ligatured and divided, and as the uterus was found to be studded with fibroids a supra vaginal amputation was then performed. The tumour was everywhere permeated with calcareous matter and there was much difficulty in making a section of it 2 Pyosalpinx (gonorrhœal ?), Enlarged and Cystic Ovaries and Parovarian Cysts 3 Sclerotic Ovaries from two cases each marked by menorrhagia and dysmenorrhœa, the ovarian envelope in the one being smooth and in the other corrugated like the surface of the brain —Dr H Macnaughton Jones showed, amongst other specimens 1
Degenerating Fibroma f
pause 2 A Microscop
an isolated encapsuled
tissue of the axilla ;
mamma of the same side, weighing over three pounds, was subsequently removed but disclosed no trace of malignancy 3 Temperature Charts and Tumour from a case in which an apparently perfect convalescence after hysterectomy in a woman, aged 55 years, was interrupted on the twentieth day by necrosis of the stump and cellulitis, leading to a hard infiltration extending half way to the umbilicus 15 days later, the condition of the patient being desperate, he made an incision from the pubes to the left iliac crest and as aspiration failed he, without opening the peritoneum, carried his incision down into the pelvis and reached a necrotic slough and a cavity containing pus (not fœtid), this was cleared out and disinfected and with subsequent drainage the patient made a good recovery —Dr Bedford Fenwick showed a Uterus with Multiple Submucous Fibroids removed from a woman, aged 54 years, seven years after the menopause For four years she had suffered from irregular and sometimes profuse hæmorrhage, relieved but recurring after the removal of a polypoid growth projecting from the cervix, again by that of a hard almost calcareous growth, and similarly on several subsequent occasions, the last mass taken away was like a piece of an orange Lately the bleeding had become more profuse, the discharge more offensive, and she had rapidly lost flesh and strength On admission to hospital a soft friable mass could be felt just inside the cervix, to the touch just like malignant disease She had a temperature of 102°F and a pulse of 110, and from the history a diagnosis of sloughing intra uterine fibroid was made The case exemplified the fallacy of supposing that fibroids did not grow after the menopause and was interesting from the manner in which it suggested malignant disease An earlier radical operation might have saved her much suffering but she made a good recovery from the operation —In the discussion which followed Mr A W Mayo Robson said that he did not think that the calcareous degeneration of fibroid tumours could be explained by deficient circulation through a small pedicle, though generally superficial it was not always so —Dr C H F Routh and Dr J A. Mansell Moullin related
itis reported by Dr
Jessett, Dr Richard
r, Mr T Rushbrooke,
also spoke and the
President and Dr Macnaughton Jones shortly replied.

PATHOLOGICAL AND CLINICAL SOCIETY OF GLASGOW —The first meeting of the session for 1903-04 took place on Oct 12th, Mr A. E Maylard, the President, being in the chair —Dr J K Kelly showed (1) a specimen of Hydronephrosis which simulated a Parovarian Cyst, and (2) specimens of Uterine Myomata removed by Operation —Dr A. N McGregor showed a girl, aged 15 years, with a large Diffuse Venous Nævus of the Thigh It had been increasing in size but treatment by ligature of several of the largest veins had led to considerable consolidation and apparent arrest of the growth —Dr John Patrick showed a specimen of a Large Congenital Umbilical Hernia The sac ruptured about 36 hours after the birth of the infant and was therefore removed, the hernia reduced, and the wound closed The patient died apparently from shock in a short time —Dr R Barclay Ness described the clinical features of a case which presented post mortem a Chronic Gastric Ulcer and Miliary Tuberculosis Specimens from the case were demonstrated by Dr A R Ferguson —Dr J MacGregor Robertson demonstrated a new form of Hæmoglobinometer (Dare's of Philadelphia) which appeared capable of particularly easy and rapid application

INCORPORATED SOCIETY OF MEDICAL OFFICERS OF HEALTH – The annual general meeting of this society
was held at
Dr Joseph C
an address o
medical office
said that spe
tamination furnished the large majority of the rural population with water while a comparatively small minority were supplied by springs from the older rocks and deep wells not liable to pollution Most of the surface water sources of supply would probably not satisfy the sanitary test of wholesome water but to a large extent their use was inevitable An agricultural drain pipe projecting through a bank and discharging water from land drainage into a ditch was a boon to many a cottager and as the pipes were laid

at a good depth to avoid the plough the water, though liable to contamination, was not necessarily unwholesome and it was often soft. Wells were the chief sources of domestic water-supply in most rural districts. The majority were surface soak wells and in the agricultural villages they were usually dip wells situated in vegetable gardens highly fertilised with pig and human manure. The simplest way to obtain a water-supply for a parish was to go to the head of a perennial stream, high up on the side of a hill if possible, to collect the water as it left the rock in a sufficiently large reservoir and to convey it in pipes to the parish. If such a plan was not practicable water must be pumped to a height from which every house in the parish could be supplied. After discussing the various methods of pumping the President concluded by saying that if he were asked how a medical officer of health might be enabled to indicate to his authority the existence of a porous stratum in which enough water was held up to supply a particular parish or combination of parishes he would say that every medical officer of health of a rural district should be familiar with the elements of the science of geology. Then with local knowledge and the aid of the drift map and the sections of the district prepared by the Geological Survey the medical officer would not be likely to lead the local authority astray.

NORTH-EAST LONDON CLINICAL SOCIETY.—This society opened its fourth session with a meeting held at the Tottenham Hospital on Oct. 8th, Dr. J. W. Hunt, the President, being in the chair.—Dr. G. E. Herman read a paper on Midwifery from the Point of View of Preventive Medicine and a discussion followed.—The officers of the society for the session 1903–04 are as follows: President: Dr. T. W. Hunt. Vice-Presidents: Dr. F. H. Daly, Mr. W. Edmunds, Dr. F. de Havilland Hall, Dr. R. Murray Leslie, Dr. E. Hooper May, Mr. J. S. Sequeira, Dr. T. Gilbart Smith, and Dr. F. J. Tresilian. Treasurer: Dr. Arthur E. Giles. Council: Mr. C. Billson, Mr. R. P. Brooks, Dr. S. E. Dore, Dr. R. E. Foott, Dr. E. A. Lermitte, Dr. G. N. Meachen, Dr. D. Petty, Dr. A. S. Ransome, Mr. T. Rushbrooke, Mr. R. F. Tomlin, Dr. A. J. Whiting, and Dr. C. H. Wise. Secretaries: Mr. H. W. Carson and Mr. C. E. Hutt.

TORQUAY MEDICAL SOCIETY.—At the opening meeting of the session held on Oct. 9th, the President, Dr. J. H. Harris, being in the chair, an address was delivered by Mr. W. Watson Cheyne entitled "Modern Surgery," in which the lecturer insisted that the great advances in operative surgery after the introduction of asepticism were due to what might be summed up in the one word "thoroughness," illustrating this by numerous cases drawn from his own practice and covering nearly the whole range of operative surgery.—The annual dinner was held in the evening and was well attended, Mr. Watson Cheyne being the chief guest.

Reviews and Notices of Books.

The Imperfectly Descended Testis: its Anatomy, Physiology, and Pathology. By W. MCADAM ECCLES, M.S. Lond., F.R.C.S. Eng., Assistant Surgeon to, and Demonstrator of Operative Surgery at, St. Bartholomew's Hospital, &c. With 44 Plates. London: Baillière, Tindall, and Cox. 1903. Demy 8vo. Pp. 140. Price 7*s.* 6*d.* net.

THE importance of the imperfectly descended testis from a pathological point of view is only now beginning to be fully recognised. Much has, indeed, been written on the subject and many cases have been reported, but very little has been done to study systematically the various misplacements of the testis and the morbid conditions to which this malposition tends to give rise. Therefore Mr. McAdam Eccles's work, which is based on his Jacksonian essay, is of the greater value as it forms one of the earliest attempts to consider adequately this important subject. Many of the abnormalities which we find in the human body are explicable only by a full knowledge of the embryology of the structure concerned and this is also to some extent true of diseases and new growths. Therefore it is natural that this work should commence with an account of the development of the testis. This is sufficiently full to explain many of the abnormalities of the organ and the description of the descent of the testis shows that its various malpositions are due to an arrest of the testis as it passes downwards. Then follows an account of the anatomy of the testis which has imperfectly descended and Mr. Eccles points out that the histological characters are very different from those exhibited by the organ when normally situated. The seminiferous tubules are smaller, shorter, and fewer in number and the amount of interstitial tissue is correspondingly increased. As to the physiology of the misplaced organ Mr. Eccles considers that the generally accepted view that it is incapable of forming healthy spermatozoa is not universally true though the exceptions are rare. This fact is of some importance in connexion with the question of the removal of misplaced testes. Moreover, though double ectopia or arrest may as a rule mean absolute sterility, yet it is probable that the internal secretion is still formed, for the virile voice and appearance are present. The succeeding chapters deal with inflammation and new growths of the undescended testis and a very interesting account is given of torsion of the cord of such an organ; several chapters are devoted to the very important subject of hernia in relation to imperfect descent. There is a close association between the two conditions as is shown by the frequency with which they occur together. The book is clearly and carefully written and, moreover, is of great interest.

Hystérotomie et Hystérectomie en Obstétrique. By Dr. V. BUÉ. Paris: F. R. de Rudeval. 1903. Pp. 454. Price 6 francs.

IN this work, for which Dr. Bué was awarded the Prix Tarnier by the French Academy of Medicine in the year 1902, the author has studied the indications for the performance of the operations of hysterotomy and hysterectomy as met with in obstetric practice. With the aid of personal observations and the experience of others he has considered in detail all the varying conditions in which one or other of these procedures may be required. In coming to a decision on this most important question it is obviously impossible to lay down any hard-and-fast rules that will be applicable to all cases, and Dr. Bué has therefore been content with quoting the opinions of all those who have written upon this debatable subject. The scope and completeness of the work will be apparent when we point out that in some 13 chapters the author passes in review the treatment of contracted pelves, eclampsia, atresia of the vagina, rigidity of the cervix, intra-uterine putrefaction of the fœtus, and pregnancy complicated by fibroid tumours or cancer of the uterus. He also considers the results to be obtained by removal of the uterus in cases of rupture of that organ and in cases of acute septic infection. The rarer indications afforded by such conditions as ovarian tumours complicating pregnancy, hydatidiform moles, inversion of the uterus, retraction of the ring of Bandl, and placenta prævia are also discussed in their relationship to hysterotomy and hysterectomy. The last two chapters are devoted to vaginal Cæsarean section and the technique of the various operations under consideration. In an appendix are given the details of nine cases of Porro's operation from the clinique of Professor Gaulard.

This monograph does credit to the author's industry and, containing as it does a large number of the opinions and observations of various writers, will prove of value as a work of reference to those interested in this important subject.

LIBRARY TABLE.

The Private Nurse's Own Note Book. By Sister EVA. London: Bemrose and Son. Pp. 96. Price 6*d.*—This is a little book containing hints to private nurses by a nurse with regard to their behaviour. The hints are sensible and, we think, needed. Sundry recipes for

"Dainty Dishes" are given, some of which are good but we cannot agree that wine jelly should be made with cornflour. The proper way to make it is with calves-feet, isinglass, or gelatin. Moreover, cornflour should not be put into a custard. Custard is, or should be, milk and eggs, with sugar and flavouring if desired. The collection of recipes which is headed "Recipes" is good. It might be as well in a future edition to explain the word "marc," for we doubt whether the average nurse knows what it means.

Practical Guide to Surgical Bandaging and Dressings. By W. JOHNSON SMITH, F.R.C.S. Eng. London: The Scientific Press. Pp. 167. Price 2*s.*—Mr. Johnson Smith is well known as an admirable teacher and in this little book we find all the clearness and practical common-sense which characterise his oral instruction. The information given will be found invaluable by nurses and dressers and even by young practitioners just starting in practice. For a young practitioner who may have been a house surgeon sometimes finds that when he starts in practice he is a little at sea without the aid of his dressers, his nurses, and the ward sister, and possibly the practitioner who has not held a resident post is in worse case, but this little book will put both of them in the right way.

Polyphase Currents in Electrotherapy. By GEORGE HERSCHELL, M.D. Lond. London: Henry J. Glaisher 1903. Pp. 44. Price 2*s.* 6*d.*—Dr. Herschell has already given some account of the therapeutic use of polyphase electric currents in his "Manual of Intragastric Technique," and in the present monograph, which is a reprint of a paper read before the British Electro-therapeutic Society in February, 1903, he has treated the subject of these particular currents in much ampler detail. He has found that the external application of triphase currents has a remarkable effect in increasing the tension and amplitude of the pulse tracing and also in increasing the excretion of urea when it happens to be subnormal. Three electrodes are used with triphase currents and for the purpose just mentioned each of them consists of a piece of felt having an area of 24 square inches and placed one on each side of the spine and one in front of the abdomen. More important still is the action of the current on unstriped muscular fibre, which renders it useful in the treatment of atonic dilatation of the stomach and in the relief of chronic constipation due to intestinal atony. On account of its effect on the blood pressure the triphase current is also indicated in various forms of neurasthenia associated with arterial hypotension. The apparatus used by Dr. Herschell for the production and application of the currents is described at some length and shown in drawings.

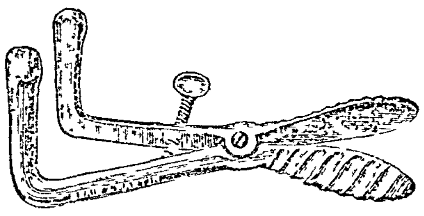
First Aid. By R. J. COLLIE, M.D. Aberd., and C. F. WIGHTMAN, F.R.C.S. Eng. London: George Gill and Sons. 1903. Pp. 125, including index. Price 6*d.* net.—It was the wise man who said "Of the making of many books there is no end," and his dictum is specially true of manuals on first aid. But the little work before us, which is by the superintendent and a lecturer respectively of the ambulance classes of the London School Board, is an excellent example of its kind. It deals with really "first aid" and does not attempt to teach too much anatomy and physiology. The book is illustrated with reproductions of photographs evidently taken from scenes which have occurred in the ambulance classes, but we think that the photograph on p. 46, showing the application of a tourniquet to the femoral artery applied *over* a boy's knickerbockers is a mistake, for anyone learning from the book without a teacher might think that the tourniquet should be applied in this way. Of course this is a mere oversight, for on p. 92 in a paragraph on the management of the clothes in a street accident the reader is told, "*Never* remove the clothes in a case of accident unless absolutely necessary—e.g., in cases with bleeding." In the paragraph on sprains, p. 27, we see that cold water is recommended; we think that hot water should have been mentioned too. Some patients much prefer hot water to cold and less harm is done if the warm application is not continuous, but if cold be employed the parts should not be allowed to become warm between the applications. The directions for the emergency treatment of poisoning are very good and so clearly written that anyone of ordinary intelligence cannot fail to understand them.

Practical Nursing. By ISLA STEWART and H. E. CUFF, M.D. Lond. Vol. II. London and Edinburgh: William Blackwood and Sons. 1903. Pp. 201. Price 3*s.* 6*d.*—When we reviewed the first volume of this excellent work we said that nurses would doubtless wait with eagerness for the second volume. They have had to wait some time, but their patience has been amply rewarded. Vol. I. was devoted to nursing in general while Vol. II. deals with the nursing of special medical and surgical cases. The first two chapters describe the nursing of enteric fever and diphtheria and are altogether admirable, more especially the directions for the feeding of a patient. Matters have certainly changed since the time of Graves who, it will be remembered, desired that his epitaph should be "He fed fevers," and nowadays we think that the tendency is to overfeed rather than to underfeed. If a fever patient shows a marked distaste for food—i.e., milk—he may, we consider, be generally left safely for 24 hours with no nourishment but plain water, or possibly water with a little egg albumen dissolved therein. Scarlet fever, measles, and whooping-cough are dealt with together in Chapter III.; but in our opinion in a future edition some reference should be made to the hæmorrhagic form of measles though possibly the authors consider that such a rapidly fatal disease has but little need for either nursing or treatment. In the chapter on respiratory diseases we are glad to see a reference to bleeding in pneumonia but no mention is made of this treatment for bronchitis; leeching, however, is given as a remedy for the acute pain of pleurisy. We need not go on to consider the rest of this work in detail, for we have said enough to demonstrate its qualities. We will only add that it is eminently practical and full of useful "tips"—e.g., the hint on p. 137 for removing the wool on a Playfair's probe by unrolling it under water and the caution against overfeeding patients suffering from extensive burns.

New Inventions.

A NEW COLOTOMY DILATOR.

I HAVE had constructed a dilator which has proved to be very satisfactory in a case under my care in which colotomy was performed. A few weeks after the operation cicatricial contraction became very troublesome. I tried two or three different kinds of dilators but found them ineffective. I therefore used rectal bougies, but their passage required considerable force and caused severe pain which frequently produced syncopal attacks lasting an hour or two. This new dilator, which is made of steel and is nickel-plated, has the general appearance shown in the illustration. Its total length is three inches and the projection of the blades, which are placed at right angles to the plane of the shanks, is one and a quarter inches. The blades are rounded off into bulbous enlargements at their ends, the inner face being kept flat so that they can be brought close together for insertion. The total separation allowed for when the blades are open to the fullest extent is two inches. The instrument has a thumb screw with a quickly running thread. After being inserted into the wound the blades are separated by means of the screw. The whole instrument has been made to occupy as little space as possible, so that when in position it lies flat against the surface of the body without any awkward projection and allows the dressing and clothes to be arranged in the same manner as when the instrument is not in use. It can be left in position as long as may be desired without causing any inconvenience to the patient. The amount of force used in producing or maintaining dilatation can be regulated to a nicety by means of the screw. I also find that it does not cause any cracking of the skin. It retains its position accurately and not only allows but facilitates the passage of flatus and discharge, the latter of which is often abundant towards the end of cases of rectal cancer. With it dilatation can be effected thoroughly and yet so gradually that it is practically painless. To maintain dilatation the instrument can be used for an hour or so each day.



I have to thank the makers, Messrs. Brady and Martin of Newcastle-on-Tyne, for the admirable manner in which they have carried out my ideas.

Dursley. R. ADAMS BREWIS, M.D. Edin.

# Analytical Records
FROM
THE LANCET LABORATORY.

(1) TABLOID IRON, ARSENIC, AND DIGITALIN; AND (2) TABLOID BUTYL CHLORAL HYDRATE AND GELSEMINE.

(BURROUGHS, WELLCOME, AND CO., SNOW-HILL BUILDINGS, LONDON, E.C.)

(1) In the compound tabloid of iron, arsenic, and digitalin the iron occurs in the form of soluble phosphate which, whilst readily assimilable, does not give rise, it is stated, to constipation. This salt is said also to be without objectionable effect on the digestive processes. Each tabloid contains three grains of soluble phosphate of iron, $\frac{1}{100}$th of a grain of arsenious acid, and $\frac{1}{100}$th of a grain of digitalin, the whole combination forming an obviously useful chalybeate tonic and cardiac stimulant. (2) The tabloid of butyl chloral hydrate and gelsemine represents a combination that is known to relieve acute neuralgia of the fifth nerve. Each tabloid contains three grains of butyl chloral hydrate and $\frac{1}{200}$th of a grain of gelsemine hydrochloride. The combination, of course, contains powerful drugs which need to be administered with particular caution.

PLASMON TEA.

(THE DIGESTIBLE TEA SYNDICATE LIMITED, 22, FENCHURCH-STREET, LONDON, E.C.)

Plasmon tea consists of a selected tea to which 10 per cent. of plasmon—the pure unaltered proteid of milk—has been added by an ingenious mechanical process. There can be little doubt of the dietetic advantages given to the tea by this proceeding. Part of the plasmon is calculated to render the tannin insoluble and inactive and part is dissolved in the beverage so that its nutritive value as well as its degree of digestibility are increased. Our analysis shows that this is the case. On estimating the amount of tannin contained in a five minutes' infusion of ordinary tea it was found to be 5 per cent. In an infusion prepared in exactly the same way but with plasmon tea the active tannin found was 2·85 per cent., so that the addition of plasmon reduces the tannin of tea by about 50 per cent. It is probable that even the tannin remaining in solution is physiologically inert and without action upon the digestive processes as it would appear to be in a neutral state combined with the proteid. The addition of more than 10 per cent. of plasmon to the tea, moreover, does not appear to remove more tannin, for the infusion contains a slight excess of plasmon, as is shown by the facts that sulphate of copper gives a decided precipitate of proteid as does hydrochloric acid also. The infusion of plasmon tea is opalescent and has a very soft and agreeable flavour recalling that of the delicate China teas. In other respects the results of analysis were normal, as, for instance, as regards the amount of caffeine and mineral matter. The nitrogen in plasmon tea-leaf (dry), however, was found to be 1·876 per cent. in excess of that of ordinary tea. This nitrogen represents approximately the amount of plasmon added. On account of this addition of plasmon there is little risk of "overdrawing" the tea and obtaining a physiologically bad infusion, whilst there remain intact the refreshing and stimulating qualities for which tea is widely appreciated. By this method the objectionable astringency of tea is removed.

ELISABETH IRON WATER (ZAANDAM, HOLLAND).

(THE ELISABETH IRON WATER AND IMPERIAL NATURAL TABLE WATER ADMINISTRATION, 9 AND 10, SOUTHAMPTON-STREET, HIGH HOLBORN, LONDON, E.C.)

The Elisabeth spring is situated at Zaandam, Holland. The samples which we examined in bottle were well charged with carbonic acid gas. The water is perfectly clear and bright and is of a yellowish-green colour. On boiling until all the gas was driven out the water still remained bright; we therefore conclude that it is free from earthy or metallic carbonates. The taste is decidedly inky and somewhat acid. According to our analysis the water yields a residue equal to 9·064 grammes per litre. These consisted of 6·290 grammes of chloride of sodium, 1·600 grammes of chloride of magnesium, 1·122 grammes of chloride of calcium, and 0·052 gramme of ferric oxide (Fe_2O_3) We do not agree with the published analysis which is to the effect that at any rate in the bottled aerated water the iron exists as bicarbonate. We rather maintain that it is present as protochloride with traces of perchloride. The water is no doubt a useful hæmatinic in certain cases and the association of salts such as the chlorides of magnesium, sodium, and calcium is valuable. The water is slightly aperient; it has been used with favourable results in the treatment of chlorosis and anæmia and in other conditions in which iron is indicated.

"LA NU" BISCUIT.

(JOHN M. MITCHELL AND CO., 33, HOPE-STREET, GLASGOW.)

"La nu" is a very palatable biscuit which shows on analysis good nutritive value. By the process of its manufacture part of the carbohydrates has been reduced to the soluble state. Thus slightly over one fifth part of the biscuit was found to be soluble in cold water. The total proteid amounted to 18·32 per cent. The biscuit is of good flavour and is crisp and uniform in texture.

BANANINE FLOUR AND BREAD.

(W. ALFRED JONES AND CO., MAY BUILDINGS, 51, NORTH JOHN-STREET, AND J. APPLEBY AND SONS, LIVERPOOL.)

There can be no doubt of the nutritious character of banana flour and the starch in it is peculiarly easy of solution and digestion in the alkaline digestive juices of the body. Banana flour is readily dissolved, for example, by the saliva. Our analysis of bananine gave the following results: moisture, 14 60 per cent.; mineral matter, 2·20 per cent.; proteid, 19·22 per cent.; fat, 2·00 per cent.; and carbohydrate, 61·98 per cent. The flour has the peculiar flavour and odour of fresh banana fruit. We have received also a sample loaf made with bananine flour. The flour proves to make a very acceptable loaf, uniform in texture and permanently moist and of a golden colour. Contrary to that which has been stated banana flour is much richer in proteid than is wheat flour and it also contains more fatty matter. Accordingly its nutritive value is decidedly higher than is that of wheat flour.

THE LANCET.

LONDON: SATURDAY, OCTOBER 17, 1903.

King's College Hospital.

As a special court of the governors of King's College Hospital held on Monday last (an account of which will be found at p. 1110 of our present issue) the removal of that institution to a site in South London was approved and formal motions were passed to enable the council of King's College and the committee of management of the hospital to acquire a suitable and adequate site and to apply to Parliament for an Act to confer the necessary powers to effect the proposed removal. In passing these resolutions the governors are supporting the unanimous recommendation of the medical staff which had previously been submitted to prolonged and anxious consideration by the council of the College, by the committee of management of the hospital, and by a special committee of influential men appointed to investigate the advisability of removing the hospital.

The most sanguine supporters of such an important change must have expected some degree of opposition. This was but natural, since in every hospital there are hallowed associations which cannot be transplanted; beds, wards, and operating theatres bear names intended to commemorate former benefactors and former workers whose labours have contributed so largely to the relief of suffering humanity and to the advancement of medical science. The names of the various wards,—Todd, Cheere, Twining, Wigram, Craven, Bambrooke, Fergusson, and Johnson—amongst King's College men evoke memories of familiar forms and though it is doubtless intended to retain these names in the new hospital they will seem less real when remote from the scenes of their work. These sentimental considerations, together with a spirit of conservatism, have perhaps weighed much with the members of the committee of the hospital who resigned when it became evident that their opposition to the scheme of removal was clearly out of harmony with the wishes of a large majority.

On the other hand, the reasons for urging the removal appear to be of overwhelming force. Dr. BUZZARD, in a conciliatory speech, briefly enumerated the chief arguments, referring frequently to a more detailed document addressed to the governors and signed by numerous members of the council and of the committee of management of the hospital. It is evident that although the hospital was originally admirably planned to supply the needs of a crowded district and to afford adequate training for medical students, it has for many years past inevitably fallen behind modern requirements. Sufficient space was originally devoted to medical, surgical, and obstetric cases, and as planned the hospital was light, cheerful, and well ventilated in all parts. In time, however, numerous special departments were created and for their proper development these required some ward space as well as properly lighted out-patient rooms. Frequent efforts were made to imp the accommodation and by re-arrangement to prov for these new departments, but the result has been produce overcrowding and consequent inconvenience in working of almost every department. The structural al tions could not be effected satisfactorily without remodelli or rebuilding a large part of the hospital. For a long ti the authorities have felt that it was imperative to constr new out-patient rooms, new quarters for the resident office and new wards for the special departments. Upon ground belonging to the hospital it has been found possible to achieve all these objects even if funds could ha been collected for this purpose.

Meanwhile, although within the hospital there have be continual growth and activity, the local need of the insti tion has been steadily diminishing owing to alterations in surroundings The building of the Law Courts and m recently the Strand improvements have cleared and populated large areas which formerly supplied numer casualties to this hospital, to St. Bartholomew's, and Charing Cross. The distribution of the hospitals in Lon has long attracted the attention of those engaged in allotment of the various charitable funds. The opinion often been expressed that while some districts are too ric supplied with facilities for obtaining gratuitous medical a surgical treatment, there are wide areas densely popula with poor people who have to travel some miles before th can obtain relief. In hospital management it is a tru that large numbers of patients invariably come from gr distances to attend the out-patient departments; that th is a process of selection or exclusion which cannot prevented and can hardly be explained. In hospitals, in private work, certain individuals or certain departme have a reputation for skill and kindliness that serves an attraction which outbalances distance or difficulty access and in this way, although through depopulat the supply of casualties may be greatly reduced, so special departments may become inconveniently crowd Those concerned with the distribution of charitable fu look, however, to an ideal distribution of the h pitals in the immediate neighbourhood of the great congestion, of the greatest distress, and from this sta point it is obvious that the Strand and Fleet-street are well supplied while South London languishes Meanwh it is on all hands admitted that ground in central Lon is so valuable that lavish expenditure must be made by a hospital attempting to put its house in order on mod lines. The rent of a requisite area would absorb too la a proportion of the income of any hospital in which it w desired to centre the best clinical teaching in every depa ment and it must be remembered that the best teach leads to the most efficient work of a hospital.

The present position of King's College Hospital in cent London possesses numerous advantages which cannot lightly overlooked. It is of easy access from all suburbs, that students may be drawn to it through almost any of channels linking town and country. It is close to College, it is close to the Royal College of Surgeons England and to the Examination Hall It is so n to the medical district that daily visits offer no gr difficulties to members of the staff. All these advanta are, however, being put aside in the desire to move with the times, to transplant the hospital to a site where it is more urgently needed and where it will be possible to construct a hospital replete with every modern device for the general and special treatment of the sick. The initial outlay involved must necessarily be very great but it is to be hoped that the self-denial and public-spiritedness of the staff in making this great step in obedience to the needs of South London will receive that financial support which will enable the scheme to be carried into effect at a very early date.

◆

The Children's Committee of the Metropolitan Asylums Board.

A DEPARTMENTAL committee of the Local Government Board was appointed in 1894 to consider the whole question of the treatment of children under the care and jurisdiction of the Poor-law and its report strongly recommended the formation of a central authority with the duty of making special provision for these children within the metropolitan area. This was the origin of the children's committee of the Metropolitan Asylums Board which was constituted in 1897 and which has recently issued its fifth annual report. The committee receives from the guardians the following classes of children: those suffering from ophthalmia, ringworm, and tuberculosis, those requiring treatment in country homes, and those children who, being mentally or physically defective, are cared for in homes in London. Homes have been opened by the committee for the reception of children under magisterial remand who, it will be remembered, were formerly, and most unfortunately, sent to the workhouse. The groups of children thus indicated, some with bodily illness and others with mental or moral deficiency, have to be cared for and educated by the State, and the report of the children's committee shows the machinery employed and the result. The sick children appear to us to be excellently treated, while the cases of psychological interest at any rate command every care. But very great skill and scientific experience should be brought to bear upon the betterment of these unfortunates.

The varied phases of educational work demanded by the conditions and special needs of mentally defective children call for much labour and special knowledge on the part of the committee, and it is impossible for us not to recognise that the *personnel* of the committee includes few among its members who are prominent in the medical and scientific world for their first-hand acquaintance with modern methods of training as adapted to the necessary end. This might, we think, be set right. The Local Government Board has the power to nominate a certain number of representatives to the Metropolitan Asylums Board in addition to the members sent by the boards of guardians, and it would be well if opportunity were made to add to the children's committee some educational authorities with the necessary knowledge and training who might assist in the discharge of the difficult and important duties which are continually extending as new social problems have to be solved in the public interest. We observe that boards of guardians do not make all the use that they might of the accommodation provided by the Metropolitan Asylums Board for mentally defective children, a condition of affairs which would probably be remedied if the children's committee were reinforced by one or two members who would be universally regarded as experts. It must be remembered that efforts for the improvement of children who are feeble-minded and physically defective necessitate the services of a more highly trained staff than may be required in cases of sickness. The children are collected from the metropolitan Poor-law schools and boarded in small homes in London under the care of a matron, so that they may attend "special classes" in the neighbouring board schools. It would probably prove more advantageous to the children, for whom town life is not desirable, if the children's committee saw its way to provide suitable homes for them out of London and a more complete educational scheme to be carried out under its own direction. Were this plan followed we should have more hope of its success in dealing with these cases after the age of 16 years; the methods of training might be continuous, each stage being planned to impart ability for future work in industrial life.

The kind of expert knowledge which, in our opinion, the children's committee somewhat lacks is in the matter of psychological training for the children who are mentally defective: those physically ill appear to be well cared for. As to the latter cases Dr. T. COLCOTT FOX, for example, gives a most encouraging account of the treatment of the children under his supervision who are suffering from ringworm. The average period of treatment required to effect a cure of the children so affected was about nine months. Dr. FOX has carefully tabulated 317 cases in his report arranged in two groups, cases of microsporon and cases of trichophyton. The former cases constitute something like 90 per cent. of the cases met with at the hospitals in the metropolis, but in the board schools it is to be noted that some 40 per cent. suffer from what has been considered a much rarer disease in London—viz., trichophyton. These latter cases came mostly from Hackney, Southwark, and Poplar. The conclusion that Dr. FOX draws is that the trichophyton may go unobserved for a long time and form centres of contagion especially apt to spread in institutions where children are collected. We instance Dr. FOX's report as an example of the kind of systematised knowledge that we should like to see infused into the treatment of the children who are mentally defective. The children's committee ought to be in a position to deal with analogous reports from psychological experts, but we find in its own report only slight indications of any effort to improve the ill-developed brains of the children under its care on any definite plan. The mere fact of a child being ignorant, dull, or stupid does not prove that he is feeble-minded; physical signs seen in defective action should be carefully noted and pointed out to the teachers as special objects for their attention. There appears to be a general idea among educational authorities that weak-minded children should have only short periods of teaching during the day, but the experience of those who are conversant with their care is that active control of these children by trained teachers throughout the day is most valuable to effect a healthy growth and to implant good methods of action. Whatever plans may be adopted in the future for the care of feeble-minded children the need of skilled teachers specially trained for these duties must be obvious.

Quackery.

ON Oct. 13th at Bow-street police-court a man named LEWIS LAMB BAILLES pleaded guilty to two summonses taken out by the Medical Defence Union, one of which charged him with using the title or description "Doctor," implying that he was registered under the Medical Acts, while the other alleged that he unlawfully, wilfully, and falsely assumed the title or description "M.B." Under the first summons the defendant was ordered to pay a fine of £20 and £21 costs or to go to prison for two months. Under the second summons a fine of £5 was imposed with the alternative of 21 days' imprisonment. The facts disclosed in the statement made by Mr. BODKIN, who appeared for the prosecution, were such as amply to justify the infliction of severe penalties and should be to some extent a warning to credulous members of the public who allow themselves to be attracted by the specious advertisements of the quack.

BAILLES, it appears, was at one time on the Medical Register with the qualifications of Bachelor of Surgery and Bachelor of Medicine of the University of Durham. He was, however, in 1894 convicted of rape and sentenced to five years' penal servitude and as the result of this conviction his name was ordered by the General Medical Council to be removed from the Register and the University of Durham deprived him of his degrees. Since his liberation from penal servitude BAILLES is said to have at one time inserted advertisements in the newspapers describing himself as having the degree of M B, but no proceedings were taken against him. At some more recent date, however, fixed by his own admission at a little more than 12 months ago, he entered the service of an American quack trading as "The Dr. McLaughlin Company" and carrying on business in England at, among other places, 164, Strand, London. The advertisements of MCLAUGHLIN must have been observed by many of our readers as well as by the general public. In some of these a statement is made to the effect that persons desiring "Electro Vigour" treatment will be under the care of a properly qualified person, and in consequence of this clerks sent by the solicitors of the Medical Defence Union visited 164, Strand, consulted BAILLES, and received from his own lips representations as to his qualifications which indorsed those made on his behalf in the advertisements. With regard to him personally we have little or nothing to say. He is no longer a member of the medical profession, having been convicted of a crime which of all others rendered him wholly unfit to practise it. Other avenues of industry are open to him and in one of these it would be wiser for him to endeavour to expiate his past and to earn an honest livelihood than to do as he has been doing. The general public, however, are liable to be soothed into security by the quack's promise of advice given gratis by a "qualified practitioner" in his employ and it should be pointed out to them that members of the medical profession who value their independence and their good name or who have a good name to lose do not hire themselves out as jackals to the advertisers of quack "remedies" for disease. Although the patients who offer themselves as victims to traders of the MCLAUGHLIN class may not fall into the hands of persons who have been convicted of felony, they will necessarily find in those who profess to treat them either men without training or qualification or men whose names should have no place upon the Medical Register, and in any case persons in the pay of unscrupulous rogues, bound by the terms of their service to push the sale of fraudulent goods to the profit of their employers.

At the hearing of the recent summonses at Bow-street police-court Mr. BODKIN said of the literature circulated by the McLaughlin Company which was in his hands that "if it were sent open through the post it would be suppressed" and that "the illustrations it contained certainly ought not to appear except in a medical work under proper supervision." No reasonable man who has ever seen any of these documents will dissent from the opinion expressed by one of the most experienced counsel practising in the criminal courts, except in so far as it suggests that the absurdities of the McLaughlin literature might find themselves reproduced in medical works. We have before us two books or pamphlets both emanating from "The Dr. McLaughlin Company" and both advocating the merits of "Electro Vigour" and the sale of the apparatus by which "Electro Vigour" is to be imparted. The illustrations, in addition to views of the McLaughlin Company's places of business, consist of pictures of men and women clothed in little or nothing but so-called electric belts and of diagrams of the belts themselves. An endeavour is made to render these pictures attractive and convincing by zigzag lines apparently representing flashes of electric sparks emanating from the belts and playing over the figures of those who wear them. Illustrations of belts for men with electric flashes radiating from suspensory attachments are evidently intended to bring home to the would-be purchaser that his sexual powers will be increased by an appliance which sets an electric current moving round his genital organs. It is to the class of persons who are ever ready to fall into the hands of the quack owing to some real or imaginary sexual weakness that the McLaughlin literature is principally addressed. Such lines as the following are specially printed in red ink in one of the pamphlets: "Second Stage of Seminal Weakness," "A Strong Appliance Cures in Three Months," "Electricity is Grand for Impotent Men." In the text we find the following passage: "Excessive indulgence in sexual intercourse has so far exhausted the power of the veins whose duty it is to throw the blood into the seminal vesicles that no response is given to the mental excitement. This is the most aggravating form of weakness—when the desire is strong in the mind but the parts do not respond. The negative current of our Electro Vigour is directed to them in those cases." While we congratulate the Medical Defence Union on its successful prosecution of an individual we cannot forget that he was merely an agent incidentally guilty of a legal offence, the trade of whose principal is not checked by the conviction obtained. We observe that before he passed sentence the magistrate desired to be informed whether anyone had been injured by the use of the "Electro Vigour" appliances. He was told that they were absolutely ineffectual for good or evil and appears to have taken this as a mitigating circumstance. It does not appear to have struck him that the sale of goods by means of statements as to their uses which are not justified by fact may involve the obtaining of money by false pretences. It seems likely that from this point of view the trade of quack medicine vendors may often be assailable where no infringement of the Medical Acts takes place, although convictions in the circumstances might not easily be obtained. In conclusion we cannot too strongly point out to those of our lay contemporaries who publish the advertisements of "The Dr. McLaughlin Company" and other such wicked enterprises that money thus obtained is dirty, filthy money, the taking of which in the long run will react unfavourably on their reputation and usefulness.

Annotations.

"Ne quid nimis."

THE USE OF THE RED TICKET IN IRELAND.

ALTHOUGH we have from time to time to call attention in THE LANCET to the treatment which is accorded to district medical officers in Ireland by boards of guardians which fail to appreciate at their just value the work of these devoted public servants, it is but rarely that we are able to record that the defaulting guardians have had to make amends for their misdeeds before a tribunal of the law. As a rule it is an expensive and uncertain process to invoke the aid of the law and, moreover, it is, generally speaking, not in the interests of a medical practitioner to enter the law courts as a plaintiff. But on this occasion we are very glad to be able to chronicle the fact that Mr. E. F. Stephenson, who is medical officer of the Woodstown dispensary district near Waterford, has succeeded in obtaining judgment against the Waterford board of guardians for payment of his claim, as also costs on the higher scale. Unfortunately, the account of the proceedings which has reached us is not as complete as we could wish but generally the salient features appear to be somewhat as follows. A vessel came into Waterford harbour from Rosario in South America and on arrival in the harbour a member of the crew was found to be suffering from small-pox. The case was duly reported to the Waterford corporation but it does not seem that that body was prepared to deal with it. However this may be, the medical officer of health apparently decided to have the patient entered as an inmate of the Waterford union workhouse and he was then sent to the isolation hospital which is situated in Mr. Stephenson's district, the medical officer of health notifying to him that the case had been sent to that institution. Mr. Stephenson thereupon visited the patient but on discovering that it was a ship-borne case suffering from small-pox he wrote to the master of the Waterford union stating the facts and asking to be informed immediately if provision had been made for medical attendance on the case. To this the master replied by wire: "Got no orders. Use your own discretion." In these circumstances Mr. Stephenson, interpreting discretion by the light of the humanity common to all medical men, visited the case, naturally expecting that the guardians would pay him for his attendance, more particularly as the clerk had previously telegraphed to him asking from what disease the patient was suffering. Subsequently Mr. Stephenson, after having treated the case for several days, wrote to the guardians asking to have his position defined, but as a result of this correspondence, in which Mr. Stephenson naturally claimed payment, he was served with a red (urgency) ticket to attend the patient, the guardians expecting by this means to relieve themselves of all responsibility as to payment. Other cases of small-pox were also sent to the hospital but these were, it appears, attended by the port medical officer of health. His honour, the judge, in delivering judgment held, we are glad to be able to record, that "the guardians from the first assumed responsibility for the case and then thought to protect themselves by throwing a red ticket at the medical officer's head." It is clear that in this case a very important principle has been at stake. Had the verdict gone against Mr. Stephenson it would have implied that a port sanitary authority might send all its ship-borne cases into the adjoining union, make them paupers, and have them treated as a matter of routine by the district medical officer. This would certainly be a convenient method by which both the shipping authorities and the port sanitary authorities could relieve themselves of their moral and statutory duties. But fortunately there are limitations to the irregular use of the red ticket and we cordially congratulate Mr. Stephenson upon his success.

SUBSTITUTION RAMPANT.

AGAIN and again in our columns we have written in strong terms in regard to the increasing practice of fraudulent substitution which would seem to respect no trade; the practice is universal and every word we have written is justified by daily events. We appeal once more for a system of strenuous control over this pernicious practice. Much of that which we eat, drink, or even wear is not what it professes to be and it seems to us that the public are for all practical purposes unprotected. Need further examples be quoted than the following which we have often quoted before? A mixture of linen and cotton is sold as pure linen, a mixture of wool and cotton is sold as all wool, a mixture of silk and cotton is sold as pure silk, goods bought as pure silk are heavily loaded with mineral matter to give a spurious impression of heaviness, grain spirit is sold as grape spirit or genuine brandy, the same spirit is sold as malt spirit or whisky, Indian tea is passed off as China tea, "plantation" coffee is sold as real Mocha, and cotton-seed oil is palmed off as genuine olive oil. Again, in jam and marmalade glucose is substituted for cane sugar and glucose is also used in place of malt for making beer. The latest addition to this infamous list is the use of cardboard wickedly sandwiched between the leather of the soles of boots offered for sale and guaranteed as "solid." A "solid" boot in the trade means an all-leather boot. The very necessity of the term implies fraud, as does all-malt in the whisky trade. And there are those in the boot and shoe trade, judging from the proceedings in a recent case, who would hold that boots with "insoles" of cardboard and brown paper might correctly be described as "solid" boots. We are glad that Judge Emden, before whom the case (a civil action be it remarked) was brought, thought differently and decided in favour of the plaintiff who sought to recover damages from the defendant for fraudulent misrepresentation in regard to the sale of boots. We have had the opportunity of inspecting a specimen of the kind of boot which was supplied in answer to the description of "solid." On ripping up the outer sole the fraud is at once brought to view in the shape of strips of cardboard inserted between the outer and upper soles. So far no other means seems to be available for laying bare the deception and it is monstrous that such a wicked fraud cannot be dealt with as a false description under the Merchandise Marks Act. A hall-mark is wanted, so to speak, which hall guarantee a "solid" boot and any misuse of the mark hould be met with the severest penalty. Anything more *razen than calling a boot solid* when by reason of its cardoard stuffing it would fall to pieces in wet weather is hard o imagine. The case of calling a piece of silk "fine heavy ilk" which is heavily loaded with mineral matter of a robably injurious kind is not one whit better. A few days go we had occasion to examine a piece of silk that ormed the sleeve of a blouse which set up an acute rritation of the skin. Analysis disclosed that the material was loaded with no less than 40 per cent. f mineral matter consisting, as further examination howed, of the oxides of aluminium and tin, with istinct traces of arsenic. Thus nearly half of the weightiness of this "silk" was due to metallic oxides. Is t wonderful that such a material worn next the skin hould set up irritation? When is the scandal of ubstitution—which is but a mild word for fraud—in such ases as we have quoted going to be adequately checked y the State? At present the evil is growing apace; dis-ussion about it soon subsides and nothing is done. If it e true that English trade is going to the dogs we think hat we can find at least one reason for this decline. To be andid, there is far too much dishonesty about it.

REPORT OF THE GOVERNMENT BACTERIOLOGIST OF HONG-KONG FOR THE YEAR 1902.

JUST at present it is the fashion to seek both commercial and *scientific salvation in the methods of every country but* our own and to echo the cry, Can any good thing come out of England? It is not easy to trace the grounds for this pessimism in the face of such a report as that now under onsideration, containing as it does a record of much sound cientific work and valuable additions made to our knowledge of practical hygiene and sanitation. That similar good work comes from all parts of the empire the article by Dr. J. Ashburton Thompson, the chief medical officer of he Government of New South Wales, which appears in he current issue of THE LANCET, gives proof. Perhaps in England there is an inherent tendency to belittle ourselves and to believe what others say in their own *promise, but one cause of the prevailing gloomy view* seems to be ignorance of the good work done, an ignorance due in many cases to the conservative traditions of many Government departments which leads to the hiding, sometimes to the extinction, of their lights under a bushel. In the Colonial office, however, at any rate this tradition should be a thing of the past. In addition to the ordinary bacteriological investigations the care and management of the public mortuary and of the Government Vaccine Institute are included in the duties of the Government bacteriologist of Hong Kong. In the public mortuary no fewer than 2816 bodies were examined in the year and Dr. W. Hunter, the bacteriologist, remarks that no institution, given suitable accommodation, apparatus, and assistance, would afford greater scope for pathological and bacteriological research. Though apparently without suitable accommodation and hampered by the loss by shipwreck of the whole of his original outfit of bacteriological apparatus Dr. Hunter has shown that this is true. Plague investigations formed, of course, a most important part of the work and between 2000 and 3000 rats were examined weekly. A most valuable series of experiments was undertaken in conjunction with Dr. W. J. R. Simpson and forms part of his report to the Colonial Office on the Causes and Continuance of Plague in Hong-Kong. By these experiments it was definitely shown that human plague was communicable to a large number of domestic animals and birds, such as calves, pigs, hens, and *ducks, and that, further, the* disease from which these animals suffered was infectious. The facility with which infection was secured by feeding is also a most important point and one not in accord with some previous work. The chronic character which the disease assumed in some of the animals would serve to explain certain peculiarities noticed in the epidemic spread of plague. Direct infection of man by food can, however, hardly be regarded as frequent and the work of Dr. Thompson goes far to show that the hypothesis of Simond that the parasites of the rat play an important part in the spread of plague is highly probable if not completely proved. As had been noticed at Capetown cats were shown to be susceptible. An epidemic of cholera gave opportunity for the important observation that in the many cases of pregnant women dying from the disease no cholera-producing organism was found in the fœtus. Investigations of certain epidemic cattle diseases and the preparation of Haffkine's vaccine and curative plague serum were also undertaken but the latter had to be given up owing to lack of suitable accommodation. The value of such a year's work is self-evident and it is to be hoped that the authorities will provide such further facilities as are required to make future work still more important.

IS IT NECESSARY TO FEEL WHETHER THE CORD IS ROUND THE CHILD'S NECK AFTER THE BIRTH OF THE HEAD?

IN almost every text-book of midwifery, whether written for the use of students or midwives, the attendant is recommended in a case of normal labour after the birth of the head to feel whether or not the cord is placed round the child's neck. If it be found in this abnormal position then he is told to slip it over the child's head or over the shoulders, or if these two manœuvres be found impracticable to divide it between two ligatures. In the *Centralblatt fur Gynäkologie* of Sept 19th is a very interesting article by Professor Schultze in which he throws grave doubts upon the correctness of this teaching. As he points out, the dangers of such a position of the cord are threefold. There is, first, the danger of the pressure of the cord upon the vessels of the neck, producing stoppage of the circulation through the child's brain; secondly, the danger of the *pressure to which the cord is in its turn subjected by the* neck arresting the circulation through the former; and lastly, the danger of the cord being compressed between the neck of the child and the anterior wall of the pelvis towards the end of the second stage of labour. Naegele was the first writer to call special attention to the last of these dangers. Veit has recorded 2250 cases of vertex presentation, in 442 of which the cord was round the child's neck. Amongst these latter the fœtal mortality was 1 in 61, and the number of children born asphyxiated was 1 in 7. In the cases in which the cord was not round the neck the corresponding numbers were 1 in 92 and 1 in 25. If, however, we consider the figures for primiparæ and multiparæ separately we find that amongst the former when the cord was round the neck the number of children born asphyxiated was three and a half times as great as when it was not and the mortality was almost twice as great, whilst amongst the latter there were no deaths, although the number of cases of asphyxia that occurred was four times as great as in cases of normal labour. Since the conditions as regards the pressure of the cord on the vessels of the neck and the pressure of the neck in its turn on the vessels of the cord would be the same in the two series of cases these figures tend to show that the main danger of this abnormality is almost entirely due to the compression of the cord between the neck of the child and the anterior pelvic wall. It is obvious that the chances of such compression *occurring to a dangerous degree are considerably greater in* the case of the prolonged second stage in primiparæ than in the relatively short second stage that occurs in the majority of multiparæ. Professor Schultze points out that as soon as the child's head is born any such danger disappears, since it is no longer possible for the cord to be compressed in this manner. In any cases, however, where after the birth of the head there are present signs of impending asphyxia of the child or of danger to his life we must proceed at once to hasten the delivery of the shoulders quite irrespectively of the position of the cord. In these circumstances, therefore, the fact that the cord is round the neck is not the ground upon which we interfere. The coiling of the cord round the neck of the child at the time the head is born does not then of necessity furnish any indication for interference and the routine practice of introducing the fingers into the orifice of the vagina at this stage of labour is not without danger. Abrasions and tears of the mucous membrane are present in many instances and the danger of septic infection is the greater in that the hand most commonly employed for this purpose will be the right one which has been guarding the perineum and is very likely, therefore, to be soiled with fæcal matter. For these reasons we may well question with Professor Schultze whether the current teaching as to the dangers of this complication and the necessity for its immediate correction does not stand in need of revision.

CULPABLE OVERLYING.

In a paper contributed to the *British Journal of Inebriety* Dr. W. Wynn Westcott discusses the subject of intemperance among women in its relation to the overlying of infants. The statistics quoted by him in this connexion are sufficiently instructive to make the most casual reader feel not a little uneasy. He informs us that during the last ten years no fewer than 15,009 infants have thus been killed by suffocation in England and Wales and that the yearly average of such deaths in London is 600 and in Liverpool 150. He further states his impression that a considerable number of cases which ought to be classed in the same category escape detection under the euphemism of "convulsions." We are also assured that deaths from overlying are exceptional on the continent and that in many German towns they are unknown. This immunity is not attributable solely to the comparative rarity of drunkenness among French and German women; it is also explained by the far more prevalent use of children's cradles in those countries than in this. In view of such facts as these it seems almost incredible that effective measures have not already been employed to bring home to the poorest class of our towns, among whom the overlying evil is usually met with, the absolute necessity of providing proper sleeping places for their infant children. There is no question of expense. An open box or basket can be utilised as a child's bed. The poor in country districts in this country use cradles. Dr. Wynn Westcott states that in the event of a verdict of manslaughter being obtained in a coroner's court when a child has been overlain it will not be confirmed in the criminal court without formal evidence of culpable neglect which, as a rule, is obviously impossible in existing circumstances. We are thus at a deadlock and it appears as if we are invited in legal terms to fold our hands in the presence of a cruel and avoidable social offence from which our continental neighbours by the exercise of a little ordinary care, assisted also by a certain humane rigour of authority, have kept themselves practically free. Intemperance is doubtless a contributory cause of overlying. We have never known it to be classed as an extenuating condition. The omission to provide suitable separate bedding for an infant is certainly neglect of a dangerous kind and being avoidable, even easily avoidable, it is certainly culpable. In what way it may best be punished we will not pretend to decide, but until it is penalised there seems but little prospect that overlying will cease to claim a still increasing number of victims.

THE RÔLE OF SOAP.

Whilst the suggestion made by a correspondent writing from Cape Colony in the *Times* of Oct. 13th that the liberal use of soap is possibly connected with the falling off in physical strength of certain classes of the community of England may on the face of it appear chimerical, yet it is difficult not to admit that the continued application of soap to the skin must rob it constantly of its natural oil. On this account soap is not calculated to make the skin supple or "velvety," a quality which is impossible without oil. Since soap removes oil it would seem perfectly correct to suggest that if soap must be used the skin should be immediately afterwards anointed with oil. Those who possess delicate complexions and who find even the best soap detrimental to the skin gain relief by the application of a soothing fat such as cold cream. The correspondent referred to writes: "The Almighty has given us a natural oil on the body to protect our skins and man gives us stuff to remove it and so expose the body to rheumatism, chills, and diseases of all kinds. Soap opens the pores of the skin, disease and dirt get in, and the body gets inoculated with any vile matter flying about." This view would be all very well if it were not for the tenacity of dirt, and this tenacity depends either upon the grease of the dirt itself or upon the natural oil of the skin. Such dirt would be hard to remove without the use of soap—plain water would never detach some kinds of dirt—and in civilised communities or in crowded cities soap thus becomes absolutely a modern necessity. In localities where grime is a rare constituent of the environment, as at sea or in the open country, the need for continual lavage with soap is not so great. There are not a few people who manage to maintain personal cleanliness without the use of soap, for there are many detergent agents besides soap, of which oil may be mentioned as the chief. But on the whole intemperance in the use of soap is not a universal habit even in civilised countries, and abstinence may answer very well on the veldt or in places far from the factory and chimney. We are convinced that soap is a really sanitary adjunct which has raised rather than lowered the standard of public health. That in isolated cases it may be used to excess we admit, but the standard of purity of soap in this country is very high and such as is calculated to prevent any injurious effects which might otherwise arise.

THE RANGOON LYING-IN HOSPITAL.

We have received a letter from Dr. T. F. Pedley of Rangoon in which he asks our opinion upon a matter of considerable interest to all those who have the charge of small hospitals in this country or in the colonies. It appears that in the year 1887 a lying-in hospital with a training school for midwives was opened in Rangoon. This hospital contained 15 beds for obstetric cases and three beds for gynæcological cases. The honorary medical staff consisted of the three senior non-official medical men practising in Rangoon and the junior civil surgeon, the senior civil surgeon acting as consulting physician. For some 15 years this institution seems to have done good work and during this time the Burma branch of the Countess of Dufferin's Fund managed to raise enough money to build a new hospital. Since the completion of the new building, and apparently by the orders of the then Lieutenant-Governor, it has been turned into a general hospital into which all classes of cases are admitted and has been placed under the charge of the chief civil medical officer of the province and the two civil surgeons, the latter gentlemen being already in exclusive charge of the Rangoon

General Hospital of some 460 beds. The cost of the new building, amounting to Rs. 109,000, was almost entirely defrayed by public subscriptions, the Government contributing only Rs 10,000. It is difficult for us to judge of the rights or wrongs of what at first sight seems to be a very high-handed procedure on the part of the local officials. It is, however, quite permissible for us to express the opinion that *the work of the hospital can hardly be very efficiently* performed by three medical men, two of whom are already in charge of a hospital of 460 beds. The question put to us by Dr. Pedley is the very important one as to whether a hospital into which lying-in cases are admitted should be used for the treatment of general cases, both medical and surgical. We say most emphatically that it should not be so used. The whole experience of those in charge of modern lying-in hospitals tends to show that they should be employed for that purpose and for no other. In this way alone can the practice of antiseptic and aseptic midwifery properly be carried out and the inmates adequately guarded against the dangers of septic infection. The transformation of this hospital intended for the reception of some 30 lying-in patients into a general hospital seems to have been initiated against the advice of the majority of the members of the medical staff, who were expelled from their honorary appointments by the orders of the Lieutenant-Governor. We presume that this gentleman did not act without some medical advice upon so purely professional a matter. His advisers, whoever they were, have incurred a very grave responsibility in running counter to the opinion of every obstetrician of note in this country or on the continent. We gather from Dr. Pedley's letter that in all probability the hospital will by the orders of the new Governor be handed over again to the local committee. We hope that this may be so and we trust that when this change is made it will be restored to the purpose for which it was built. In this way alone can the best interests of the institution and of its inmates be served and the danger as far as possible avoided of the occurrence of cases of septic infection—an occurrence which in the existing circumstances would be little less than a public scandal.

THE VALUE OF TETANUS ANTITOXIN.

THE exact value of tetanus antitoxin is even now still *sub judice*. That it is able to neutralise the toxin if injected before or soon after the injection of the toxin has been conclusively shown in animals. In man, however, where the experimental method of investigation is inapplicable, the only cases in which we can observe the action of the antitoxin are those in which the disease has already developed. From the knowledge we possess of the pathology of tetanus we can be quite sure that by the time symptoms of spasm become first manifest the disease has progressed so far that the antitoxin is not capable of exhibiting all its curative power. There is still much that is obscure in the pathology of tetanus but we know that the phenomena of the disease are produced not by the direct action of the specific bacillus but by the toxin to which this bacillus gives rise. The bacillus is confined to the wound and the toxin alone is absorbed. After absorption into the blood stream it is carried to the central nervous system and there the greater part of the toxin enters the nerve cells and forms a very stable compound with the cell substance. When the antitoxin is introduced it can neutralise any "floating" toxin which is still in the circulation but it is unable to break down the very firm union between the toxin and the cells of the central nervous system. Therefore it is clear that as soon as any spasms appear the time has gone by for the most valuable action of the antitoxin, for the action of the toxin on the nerve cells has already commenced. It is true that the antitoxin can still render innocuous that portion of the toxin which is unfixed and any further amount of toxin which may subsequently be absorbed, but the effect already produced on the nervous system may have been sufficient to lead to a fatal issue. Without the employment of the antitoxin recovery ensues in a certain proportion of cases of tetanus, especially when the incubation period is long, that is, over 12 or 14 days. When a large quantity *of the toxin has been absorbed the symptoms develop* rapidly and even if the antitoxin be administered early it cannot exert its beneficial action, for a large amount of toxin has already attacked the cells of the central nervous system. Thus it comes to pass that the mortality of the cases in which the antitoxin is administered early is very high. Ullrich collected 41 cases in which the antitoxin was injected within 30 hours of the commencement of symptoms and the death-rate was over 72 per cent., while in 72 cases in which the antitoxin was injected between the second and fifth days the mortality was less than 46 per cent. In spite of these statistics there is good evidence that antitoxin is of distinct value in tetanus, especially if it be administered early, and in the present issue of THE LANCET we publish an account of a case under the care of Dr. J. W. Cook at the Bury Dispensary Hospital. In this case the antitoxin was injected and improvement appeared to follow and when the injections were omitted on one day a slight relapse occurred. We consider that the successful result was rendered more certain by the use of the antitoxin, though the patient might have recovered without it as it was not an acute case. The employment of the antitoxin, however, should not lead us to neglect the local treatment. The bacillus lives only in the wound where it forms toxins which are absorbed. To permit, therefore, the tetanus bacillus to continue its formation of toxin in the wound is to invite failure. The wound should be opened up and cleansed with the greatest care, all foreign bodies and necrosed tissue being removed and the wound being rendered aseptic. By thus cutting off the supply of toxin the surgeon is better able to deal with the quantity which has been already absorbed.

THE CLASSIFICATION OF PAUPERS.

THE holding of conferences is apt to be rather unproductive as regards practical results, mainly because any suggestion of value is lost in the sea of words which inundates it. Only too frequently have the meetings of guardians and Poor-law officials served to illustrate this statement but we trust an exception to the rule may be provided in the case of the delegates from the Lancashire and Cheshire unions who met lately at Blackpool under the presidency of Sir John T. Hibbert, K.C.B. Quite an unusual amount of common-sense seems to have been brought to bear upon the important matters of workhouse management and parental responsibility but a paper on the Combination and Classification of Workhouses by Mr. H. P. Cleaver, clerk to the West Derby Union, invited and received special attention. In advancing a plea for the improved classification of paupers Mr. Cleaver expressed the opinion that the difficulties met with in the treatment of pauperism could be dealt with to better purpose by some system of voluntary amalgamation and he suggested the formation of joint committees of boards of guardians to look, respectively, after vagrants, imbeciles, lunatics, and the other classes into which the indigent fall. It was decided to submit these views to a special conference convened for the purpose. If properly carried out the idea of separating the various groups of paupers by housing them in distinct buildings is an excellent one. Any virtue that lay in the proposal to transfer the administration of the Poor-law from boards of guardians to the county councils was dependent on the opportunities which would thus have been afforded of elaborating a scheme of classification. In

London the problem would be a fairly simple one, since by a combination of the various unions the existing buildings could be allotted to the different subdivisions which it might be found convenient to recognise. Improved classification is at any rate urgently demanded to overcome the numerous abuses to which the present system gives rise and if the members of the north-western conference can help to devise a workable arrangement they will earn the gratitude of the many who have the interests of the poor at heart.

SUDDEN RISE OF BLOOD PRESSURE AS AN EARLY SIGN OF PERFORATIVE PERITONITIS IN TYPHOID FEVER.

THE trend of surgery, as was recently shown in Mr. Donald Armour's paper,[1] is to treat intestinal perforation in typhoid fever by immediate operation. The dictum of Keen to wait until shock has passed off is being abandoned. Hence the great importance of early diagnosis of perforation. In the Boston *Medical and Surgical Journal* of Sept. 24th Dr. J. B. Briggs, resident house officer of the Johns Hopkins Hospital, at which so much work has been done to advance the surgery of typhoid perforation, has recorded some new observations showing that the blood pressure rises with the onset of perforative peritonitis before pain or other symptoms develop. Whether his conclusion that this rise is a trustworthy guide to early operation be borne out by wider experience or not his observations are a valuable contribution to pathology. In the past two years Dr. Briggs has frequently observed with the Riva-Rocci sphygmomanometer a sharp rise in the systolic blood pressure on mechanical stimulation of the peritoneum during laparotomy. Dr. Harvey Cushing suggested that a similar rise possibly occurred at the onset of perforation in typhoid fever from peritoneal irritation and might prove of value in early diagnosis. Dr. Briggs found that in acute peritonitis except when the patient is moribund the pulse tension is high. During the past year the pulse tension of the patients suffering from typhoid fever in the Johns Hopkins Hospital was closely observed. In two cases in which there were symptoms that led to laparotomy the observations of blood pressure are of great interest In the first case a young man was admitted about the end of the second week of a severe attack. During the next ten days the abdomen was soft and natural and from 20 to 200 measurements of systolic blood pressure were made daily. The pressure ranged from 98 to 115 millimetres of mercury and tended to fall as the disease progressed. At 8 P.M. one night the pressure was 106 millimetres. At midnight it was 144, when there were no abdominal symptoms. At 4 A.M the patient suddenly cried out with severe abdominal pain; his knees were drawn up, abdominal respiration was restricted, and there was great tenderness over the lower part of the right rectus muscle which was rigid. The symptoms rapidly developed, laparotomy was performed five hours later, and two perforations were found in the ileum. There was rapidly spreading peritonitis and pus was found in the pelvis. Before operation there had been no sudden fall of temperature and the leucocytes showed no change in frequent counts. The blood pressure remained high, falling slightly in the hours preceding operation. In the second case a young woman had a severe attack of typhoid fever. At the end of the first week of a relapse and on the fifty-seventh day of the attack grave abdominal symptoms occurred. In the preceding six weeks the blood pressure ranged between 104 and 125 millimetres of mercury. For some days abdominal pain had occasionally been complained of and there had been some tenderness on deep palpation which was never well localised. The abdominal distension rapidly increased, the pain became greater and more constant, and the tenderness increased while remaining general. The distension progressed and could not be relieved by the administration of turpentine by the mouth or by enemata. The pulse rose from 150 to 172 and the leucocytes from below 7000 to 17,000 per cubic millimetre. As perforation was thought probable laparotomy was performed. During the relapse the blood pressure ranged slightly below 120 millimetres and during the period of abdominal symptoms it was about the same, rising occasionally to 125 In the absence of any abrupt rise of blood pressure Dr. Briggs expressed the opinion before operation that perforation had not occurred. None was found and a filmy covering over two ulcers was the only sign of peritonitis. In the first case it is remarkable that the rise of blood pressure occurred so long before other symptoms of perforation. At the operation the peritonitis appeared to be of eight or ten hours' duration, which would correspond with the sudden rise of blood pressure. Dr. Briggs thinks that perforation must have preceded the rise of pressure. Perhaps extravasation took place first among the intestinal coils and pain was not felt until the inflammation reached the parietal peritoneum. Magendie long ago stated that pain could not be provoked in a part supplied by the sympathetic nerve—a view recently confirmed by Professor Lennander of Upsala.[2]

THE LUNACY PROBLEM IN LONDON.

THE fourteenth annual report of the Asylums Committee of the London County Council refers to the character and growth in numbers of the insane in the county of London during the year ending March 31st, 1903. The report begins by stating that once more it is necessary to chronicle a large increase in the number of certified lunatics. Thus on Jan. 1st, 1903, the total number of patients chargeable to the county of London was 16,689, being an increase of 639 over the corresponding number for the previous year. In a table dealing with the entire pauper lunacy population of London since 1890 it is shown that whereas on Jan. 1st, 1890, the lunacy population amounted to 16,358 patients, in 1895 it reached 18,541, in 1900 it amounted to 21,393, and in 1903 to 22,952. Taking, however, the pauper lunatics whom the London County Council alone, apart from other public bodies, is called upon to find accommodation for the figures are 10,100 for 1890, 12,108 for 1895, 15 061 for 1900, and 16,689 for 1903. It is thus evident that during the period 1890 to 1903 the total pauper lunacy population of London under the jurisdiction of the County Council and of other bodies has shown a steady increase. This is graphically illustrated in a chart (Table 2) attached to the report, showing the comparative rates of growth year by year of lunacy and of pauperism in relation to the general population. A simple calculation founded on the figures embodied in the chart shows that whereas during the 14 years (1889 to 1902 inclusive) the general population of London has increased by 11·4 per cent., its total lunacy population has increased by 38·9 per cent. It would appear from this that lunacy in London increases at a much more rapid rate than does the general population. There is, however, some doubt whether the increase is quite as rapid as the table indicates, for whereas 20 years ago a considerable number of unregistered lunatics lived with their relatives and friends nowadays they are taken with less reluctance to receive asylum care and treatment. Such a factor cannot operate, however, for an indefinite period of time and, moreover, its effect tends to be reduced to uniformity after a few years. The public asylums of London have been under the jurisdiction of the County Council only during a period of 14 years and the increase shown within that period seems to be mainly in continuity with the increase of the decade preceding it, so that the mere factors of "accumulation" of chronic cases and greater inclination to enter an asylum lose their force in an attempt to account for the steady and accelerating rate of increase of lunacy. Attention to these points, which are necessary to enable correct conclusions to be reached in regard to this question, has been drawn in leading articles and annotations in THE LANCET[1] in previous years. The London County Council has been vigorously coping with this increase of lunacy by building several asylums since it took charge of the lunatics of the county. Thus within the last decade it has opened asylums at Claybury, Bexley Heath, and Horton, and has provided an epileptic colony at Ewell. Since the last report a plan for a new asylum has been, and now is, under the consideration of the subcommittee for the housing and treatment of lunatics. The report refers to the recent disastrous fire at Colney Hatch Asylum and to the precautions taken at all institutions subsequently to that event in order to deal with unexpected outbreaks of fire. The special returns from the several asylums show that the average numbers of patients resident in each were as follows: in Hanwell Asylum it was 2544, in Colney Hatch 2490, in Banstead 2453, in Cane Hill 2139, in Claybury 2398, in Bexley Heath 2079, in the Horton Asylum 958, and in the Manor Asylum (Epsom) 685. The average number for all the asylums was, therefore, 15,746 patients. The total number of patients admitted to the asylums during the year was 4978. Of these 4579 were first admissions. The number discharged as recovered amounted to 1159 or 7·36 per cent. of the average number resident. The deaths during the year amounted to 1519, or 9·6 per cent. as calculated on the same basis. During the financial year ending March 31st, 1903, the weekly cost of maintenance has averaged 11*s.* 5*d.* per patient and the uniform weekly rate charged to the parishes and unions within the county was 11*s.* 8*d.* The result of the year's working has been an aggregate profit from this source of £12,925.

---

GASTRIC EROSIONS.

IT is now fully established that there exists a condition of the stomach in which profuse gastrorrhagia may occur and yet no real ulcer may be present. On the gastric mucous membrane are found minute erosions from which during life blood may be seen to pour in an almost continuous stream. Dieulafoy, who first described gastric erosions, distinguished two varieties; the one he called simple erosions and described them as mere surface abrasions of the mucous membrane, and the other he named "exulceratio simplex," in which the lesion is sufficiently deep to lay bare the vessel under the muscularis mucosæ. These distinctions are probably of no great importance but both of these varieties can give rise to the most profuse hæmorrhage, and yet after death the simple erosion may be easily overlooked but during life the blood is seen to come from numerous points in the mucous membrane. The onset is generally very sudden; in fact, the suddenness of onset may be of some little value in diagnosing the erosion from a gastric ulcer, for in the case of the gastric ulcer it is quite exceptional for the onset to be sudden. Another point to be considered is the profuseness of the hæmatemesis. A sudden and profuse hæmorrhage from the stomach is much more likely to result from an erosion than from a gastric ulcer. The most suitable treatment for this condition is still undetermined but surgery offers the best chance, for gastric rest and the administration hæmostatics, even of adrenalin, seem to be of little avai When the stomach has been opened the bleeding area c be surrounded by a purse-string suture and thus the bleedir may be controlled. A case of gastric erosion successful treated in this manner was in St. Bartholomew's Hospital the end of last year under the care of Sir Dyce Duckwort and Mr. H. T. Butlin, who communicated a paper on the ca at the meeting of the Clinical Society of London on Oct. 8t a report of which will be found on p. 1057 of our prese issue. The severity of the hæmorrhage seems to preclu any delay and the procedure adopted by Mr. Butlin appea to give the best chance of a favourable issue.

THE BIRMINGHAM CREMATORIUM.

THE opinions of men whose minds are diversely swaye by science and by religion may well be expected to disagr on such a subject as the disposal of the dead. Happil however, not only are scientific men often religiou but also religious men are often scientific. The possib harmony between representatives of the two types intelligence was well illustrated at the recent openin ceremony of the Birmingham crematorium. Sir Henr Thompson and Sir Oliver Lodge were more explicit o but no more enthusiastic upon, the advantages of crem tion than were the Bishops of Worcester and of Coventr That there is still in this country a great deal of objectio to cremation, based upon ideas of mistaken sentiment an mistaken religious feeling, is undoubted. We hope th the words of the Bishop of Worcester on the occasion which we refer will come to the eyes of all who hold thos erroneous ideas. The Bishop said in a letter read at th opening ceremony of the crematorium, "What I shoul desire when I myself die is that my body should reduced rapidly to ashes, so that it may do no har to the living, and then in accordance with Christia feeling be laid in the earth." Similarly the Bishop Coventry wrote that "in spite of strong sentimental obje tions very naturally entertained, we shall come to see th under the conditions of modern life cremation is not onl preferable from the sanitary point of view, but that it is als the most reverent and decent treatment of the bodies of th dead." Sir Henry Thompson's address dealt with the histor of the cremation movement from its origin in 1874. H referred to the passing of the general Act last session and the certain increase of cremation in the future. The pr ceedings at the opening of the Birmingham Crematoriu should go far to impress the minds of any who study the with a sense of the desirability of cremation whether viewe from a religious or from a scientific and sanitary standpoint.

THE METROPOLITAN WATER-SUPPLY.

THE report on the condition of the metropolitan wate supply for the month of August has been published. Th Thames river water at Hampton, Molesey, and Sunbury wa in good condition from the first to the twenty-fourth and fro the twenty-eighth to the thirty-first days of the month; o the twenty-fifth and twenty-sixth days it was, according the statement of the engineer of the Chelsea Waterwor Company, of "bad," and on the twenty-seventh day indifferent, quality. In the absence of Dr. T. E. Thorp F.R.S., the chemist appointed by the Local Governme Board, the analytical work was apparently undertaken "H. J. Helm," for so the report is signed. One full analys was made of one specimen of the water supplied each company on August 18th. It was found that th relative amount of organic impurity in the waters examine might be numerically expressed as follows: Kent New River 19, West Middlesex and Grand Junction 3

---

[1] The Lunacy Problem and Official Statistics, THE LANCET, August 31st, 1901, p. 603; The Lunacy Problem as it affects London, THE LANCET, Sept. 27th, 1902, p. 880.

Chelsea 37, Southwark 40, East London 42, and Lambeth 49. It does not appear that any specimen of the water supplied by any company was "fully examined" either during or after that period of the month during which the river water of the Thames was in an indifferent or bad state. This fact may be worthy of the attention of the London Water Board and of the representatives of the metropolitan borough councils.

HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST, BROMPTON.

THE course of lectures for the winter session will be opened by Dr. S. H. Habershon by two lectures on Bronchiectasis on Oct. 21st and 28th at 4 P.M. These lectures will be illustrated by cases and are free to all qualified medical practitioners and to students of medicine. The lectures have hitherto been very badly attended. In fact, this is probably owing to the large number of other post-graduate courses in existence, and yet the Brompton Hospital for Consumption and Diseases of the Chest possesses ample valuable clinical material. The authorities have now decided to throw the lectures open to students as well as to qualified men and we most earnestly hope that advantage will be taken by both classes to attend these lectures which deal with forms of disease which are only too common, which are protean in their manifestations, and which are so very frequently met with in private practice.

THE autumn meeting of the South-Eastern Division of the Medico-Psychological Association will be held, by the courtesy of Dr. William Rawes, at St. Luke's Hospital, Old-street, E.C., of which he is medical superintendent, on Thursday, Oct. 29th. The programme is as follows: 1.30 P.M., members invited to luncheon; 2.15 to 3 P.M., inspection of the hospital; 2.15 P.M., meeting of divisional committee; 3 P.M., general meeting, when the time and place of the spring meeting of the division will be fixed and Dr. Rawes will give a short history of St. Luke's Hospital and Dr. F. W. Edridge-Green will open a discussion on "The Relation of Hysteria to Insanity." At 7 P.M. the members will dine together at the Café Monico, Piccadilly-circus, London, W. Communications should be addressed to the honorary secretary, Dr. Arthur Norman Boycott, Herts County Asylum, Hill-end, St. Albans.

THE medical officer of health of the Cape Colony reports that for the week ending Sept. 19th no case of plague in men or animals was notified, except at East London, where plague-infected rats were found. As regards the Mauritius, a telegram from the Governor received at the Colonial Office on Oct. 9th states that for the week ending Oct. 8th there were 91 cases of plague and 54 deaths from the disease.

THE Odontological Society of Great Britain announces that it is prepared to receive applications for grants in aid of the furtherance of scientific research in connexion with dentistry. For particulars and forms of application inquiry should be made of the honorary secretary, Scientific Research Committee, Odontological Society, 20, Hanover-square, London, W.

WE regret to announce the death of Sir George F. Duffey, formerly President of the Royal College of Physicians of Ireland, which occurred at his residence in Ireland on Oct. 13th. Sir George Duffey was in his sixty-first year.

MR. George Lawson, F.R.C.S. Eng., who was surgeon oculist in ordinary to Her Majesty the late Queen Victoria, died on Monday afternoon last at 12, Harley-street, Cavendish-square, W.

KING'S COLLEGE HOSPITAL.

THE governors of King's College Hospital have resolved to remove the institution from its present position in Portugal-street, Lincoln's Inn, London, W.C., to a site in South London not yet decided upon at a cost of upwards of £300,000, which it is hoped that the public will furnish. Founded 60 years ago as a local charity and a medical school for King's College the hospital is housed in a building which the medical staff of the institution has unanimously condemned as not only inadequate in accommodation but also obsolete in design, insanitary in arrangement, and wholly behind the hygienic requirements of the day; the method of construction and the extremely narrow limits of the site upon which the building stands being such that even the expenditure of £100,000 in patching it up would not bring it near the standards of modern science and hygiene. Moreover, while the hospital has undoubtedly long met a definite local need, the conclusion has lately been forcing itself upon its managers and others specially interested that it can no longer be said to do so because of the clearances in connexion with the Strand improvements and the migration of population from its neighbourhood to districts north of Holborn and south of the Thames. Only "a few poor streets" form its present "immediate vicinity" and for cases from among the dwellers there ample accommodation exists in St. Bartholomew's, Charing Cross, and the Royal Free Hospitals; but the vast area and population between Wandsworth and Greenwich particularly need the advantages which can be furnished only by a large general hospital. When removal was seriously put forward on the initiation of both the council of King's College and the committee of the hospital some members of the committee, regardful of the associations and sentiments which have arisen around the institution and the magnitude of the scheme involved, offered the proposal a mild opposition and followed that by resigning membership, and the majority left were not quite sure how the general body of governors would view the matter.

A special court of the corporation of the president, vice-presidents, and governors was held on Oct. 12th in the large theatre at King's College in order to put the question to a proper test. Mr. W. F. D. Smith, M.P., one of the vice-presidents, who had acted as chairman of the committee in connexion with the removal question, was called upon to preside there was a fairly representative attendance. The secretary (Mr. H. S. TUNNARD) read letters from H.R.H. the Duke of Cambridge, the Archbishops of Canterbury and York, Lord Lister, Sir Albert Rollitt, M.P., and others, expressing inability to be present and their approval of the proposal.

Mr. SMITH explained that as the hospital had been founded under an Act of Parliament it was impossible to deal with the building or the land upon which it stood without an amending Act, the promotion of which it was necessary should be sanctioned by the governors. The legal aspect of the case had been examined by the solicitors to King's College who had framed a motion empowering application to Parliament for a Bill. He hoped that the policy embodied in the motions to be proposed would be adopted by such a majority of those then assembled as to render further meetings on the subject unnecessary.

Dr. T. BUZZARD, in the absence of Lord Lister, moved:—

> That this court approves of the proposal to remove King's College Hospital to a site in South London.

In supporting this proposal he said that the hospital was one which by lapse of time had become inefficient for its purposes as a hospital, because the science of hospital construction and arrangement had progressed very much indeed since it was built. Moreover, from other circumstances it had ceased to be of the value to the poor which it originally possessed. He was a resident medical officer in the original King's College Hospital 50 years ago and he could tell of the extraordinary change which had taken place in the neighbourhood in that half century. So great was the alteration that he had not the least doubt of the necessity for removal and he hoped the governors would agree to his motion, for he could assure them that the scheme had met with the most studied and careful consideration of those who were responsible for it. He thought they would be doing a great public duty in removing from central London, where so many large hospitals were crowded together at no great distance from each other, and in finding a place comparatively in the suburbs to which [illegible] every hour. They must not [illegible] was an important part of the [illegible] p pace with the advance in medicine and surgery it was imperative to obtain more room and greater extension of equipment than the present building could furnish. The existing deficiency was acting prejudicially against the medical school, for students would not come where the requirements of modern science were not to be had.

Mr. C. AWDRY, in the absence of the Bishop of Exeter, seconded the motion. As treasurer he had carefully considered what was their duty at this juncture in view of the large amount of money the scheme involved and he had reluctantly come to the conclusion that it was necessary to remove the hospital to a site where it would more fully meet the generous and charitable designs of its founders.

Mr. S. J. WILDE, one of the oldest subscribers, said he must vote against the proposal. He had known the district for a great many years and while it was quite true that the character of the neighbourhood around the hospital had changed there were many people living there still. Charing Cross Hospital was not in a poor neighbourhood, yet it was being extended at a very large cost, which showed the necessity of its continuing where it was. He was afraid that removal would be a step towards severing the hospital from the College. If, however, removal was necessary this was a very inopportune time for it because so many other central hospitals were begging at present and the sum wanted for the new King's College Hospital was a very large one.

Lieutenant-Colonel CLIFFORD PROBYN moved as an amendment—

> That the further consideration of the motion to remove the hospital be postponed for a period of two years.

He believed that by that time many of the poor who had been disturbed by the Strand improvements would be re-established in the district and they would then know better what to do

Mr. WILDE seconded the amendment.

Mr. H. S. COLLINS, who had given £1000 to the hospital entirely because of local sentiment, pointed out that if removal took place such contributions would cease. He regarded the expenditure on Charing Cross Hospital as a great waste of money and thought that on charitable grounds there should have been some communication between that hospital and King's College to see whether the two could not be brought together.

The Rev. Dr. HEADLAM, Principal of King's College, stated that it was quite true nine or ten members of the committee of management had resigned, but he understood that their opposition arose not from objection to the removal but on account of the difficulties that would have to be faced in connexion with the scheme. They all felt there would be difficulties, but if they were convinced that removal was right and would be beneficial they ought to face these difficulties, put their needs before the public, and do their best to carry out the proposal. The enlargement of Charing Cross Hospital was a reason for the removal of King's College, because there was room for one but not for two, and their medical students had to go further and further afield for the training that was necessary to them. He hoped that in moving to South London they might be able to meet a great need and be able to build a hospital which was up to the standard of modern requirements.

Mr. M. M. McHARDY urged that the site to be looked for should be adequate and suitable for a building to provide 600 beds.

On a show of hands the amendment, which secured only six supporters, was rejected. The motion was then carried, only five hands being held up against it.

Mr. SMITH, in answer to questions stated that there would be plenty of money available to secure at least a suitable site which in his view should be "on the centre of the fringe of South London."

On the motion respectively of Dr. D. FERRIER, seconded by Mr. W. WATSON CHEYNE, and of Colonel FELLOWS, seconded by Mr. WILDE, the joint committee appointed by the council of King's College and the committee of management of the hospital was authorised to acquire a suitable and adequate site, and to apply to Parliament for an Act to contain any powers necessary to carry out the removal of the hospital and power to sell, mortgage, lease, or otherwise dispose of the present site.

ANNUAL REPORT (1901-02) OF THE MEDICAL OFFICER OF THE LOCAL GOVERNMENT BOARD.[1]

III.

BEFORE concluding our notice of the inspections made in 1901–02 by the medical staff of the Local Government Board (the details of which fill about 230 pages of Mr. W. H. Power's report), we think it right to comment very briefly on the question of sanitary administration generally, as suggested to us by a perusal of the reports of the several inspectors. Our library contains a goodly number of reports by successive medical officers of the Board, from Sir John Simon onwards, every volume of which furnishes particulars of local investigations made by experts of acknowledged competence concerning some of the more glaring instances of sanitary delinquency brought to light during the year. On turning over, at random, the pages of any one of these volumes we meet with case after case of grave neglect of statutory duty by sanitary authorities, almost always culminating in more or less serious outbursts of preventable disease. When it is realised that only in the rarest instances are these inquiries directed by the Board, unless either at the urgent request of some defaulting authority apprehensive of financial loss from deserted lodging houses, or else on the petition of actual sufferers from the neglect of their statutory protectors, we are constrained to ask what is the sum-total of loss of life and health that is caused annually in this country, and especially in our "health resorts," by the greed, the ignorance, or the apathy of the authorities who are the appointed custodians of the public health.

We do not possess the means to answer this question but it is certain that the Local Government Board—advised by its own medical staff and kept informed on health matters by an army of medical officers of health stationed everywhere for this very purpose—must be cognisant of the local sanitary shortcomings of which we are allowed to see an occasional example but the full extent of which the Board refuses to make public. The Board unquestionably possesses the power to call to account the authorities responsible for the neglect referred to and we are astonished that English public opinion has not long ago protested against the continued application of mere palliatives for the removal of an acknowledged national danger.

In numerous recent instances we have found it desirable on public grounds to direct attention in our columns to the accumulations of insanitary conditions against which medical officers of health have to contend in their efforts to conserve the health of the people—conditions of which Dr. H T. Bulstrode supplies a striking and typical example in his present report on the sanitary state of Whitehaven. As an excuse for inaction in similar circumstances it is often contended by sanitary authorities that in order to deal effectually with [illegible] wholesale demolition [illegible] permanent avail and [illegible] ople required by law would involve local financial ruin. We are, of course, familiar with this specious reasoning and equally so with the appeal *ad misericordiam* which often effectually accompanies it. Considerations of this kind may probably have weighed with the Local Government Board and may have induced it to deal leniently with authorities which unfortunately inherit statutory responsibility for defects not of their own causing and which are doing something at least for their removal. But what excuse can be made on behalf of district councils which are perpetuating the same evils in cottage property now actually in course of construction? Why does the central authority tolerate the covering of vast areas of land with dwelling-houses which, built in defiance of sanitary knowledge, will in a few years present conditions hardly better than those which render the slum property of our older towns unfit for human habitation? To both these questions the answer is too obvious to require formal statement.

The speculative builder of to-day avoids the territory of our great municipalities where, at any rate, some regard is paid to the durability of houses built within their jurisdiction. He directs his attention generally to the confines of populous towns, to suburbs where sanitary matters are in the hands of district councils composed mainly of petty tradesmen who equally with himself are anxious for the rapid extension of house building. Being in appearance a man of affluence the speculative builder readily obtains a seat on the district council and, devoting much attention to local affairs, he speedily rises to an influential position among his fellow councillors. He then proceeds to acquire possession of every available acre of land in the district and to erect thereon row after row of cottages which will stand long enough to enable him to dispose of them to his own satisfaction and to repeat the same process elsewhere, probably in a distant part of the country.

---

[1] Previous notices of this report were published in THE LANCET of Sept. 19th (p. 839), and of Oct. 3rd (p. 972), 1903, respectively.

Within less than a score of miles from where we write, in districts fringing the metropolis and beyond the reach of London by-laws, thousands of cottages are now being erected, many of them are water-logged and others are on "made" land—cottages which if built within the metropolitan area would not pass muster for a day. But what is particularly distracting from the Londoner's point of view is this—that the sites now being covered with sparely built houses will almost certainly be absorbed into the metropolitan area not many years hence; in which event the successors of our present borough councillors will have to deal with what will then have become unhealthy areas after the manner in which certain of the older areas of London are at this moment being dealt with.

From the preventive standpoint that portion of Mr. Power's report which deals with the Board's administrative action in relation to the London small-pox epidemic in the period to which his report relates is full of interest and instruction. From the beginning of the epidemic to the end of March, 1902, the notification of cases of small-pox in London amounted to about 6000. But although this total is a large one it must not be inferred that London in its entirety suffered heavily from the disease. In the later months of 1901 St. Pancras, St. Marylebone, Holborn, and Bermondsey, and in the earlier months of 1902 Shoreditch, Bethnal Green, Stepney, Poplar, St. Pancras, Hackney, Southwark, Camberwell, and Battersea suffered most severely from the epidemic. But even in these boroughs the disease did not involve more than limited sections of the population, whilst not a few boroughs were from first to last comparatively free from small-pox. The Board in its capacity as the sanitary intelligence department of the State—always alive to the risk of the importation of small-pox from abroad and mindful of the scandalous neglect of vaccination in London to which we have already referred—took exceptional pains to bring about, through its medical staff, better administration of the vaccination law by the guardians, forcibly reminding them of their responsibilities in connexion with the epidemic.

Circulars were addressed to the borough councils urging upon them the necessity for energetic action with a view of limiting the spread of infection, such, e.g., as the medical examination of all notified cases and their immediate isolation in hospital, the disinfection of houses and bedding, and the vaccination of so called "small-pox contacts." The Board further adopted the unusual course of requesting that its medical department should be kept supplied with precise information of the measures which in each case had been taken by the local officers to check the spread of infection. The London School Board was also approached and its attention was directed to the large proportion of unvaccinated children in certain small-pox stricken parishes; it was urged to encourage the prompt vaccination of such children with the hope of preventing the spread of infection by contact in school. The School Board thereupon promptly resolved to afford facility under reasonable conditions to the vaccination officers of the metropolis to enter the schools belonging to the Board in infected areas and to examine the arms of children with a view of inducing parents to allow the vaccination of those who were unprotected. At a later date the Local Government Board communicated further with the metropolitan borough councils to the effect that cases of small-pox were frequently escaping detection owing to their being mistaken for chicken-pox; it was therefore suggested by the central authority that chicken-pox should be included in the list of diseases the notification of which is compulsory under the London Public Health Act. It will be remembered that this action of the Board led subsequently to the addition of notified cases of chicken-pox to the weekly returns of cases of infectious disease in London published by the Registrar General. Referring to the splendid services rendered by the Metropolitan Asylums Board in combating small-pox Mr. Power writes thus: "Here it is not necessary to say more than that, under circumstances of exceptional difficulty and pressure, the authority in question expanded and increased both its hospital accommodation and its land and river ambulance service so as to keep pace always with the demands of the metropolis. Throughout the epidemic no disadvantage to London arose by delay of removal of small-pox patients from their homes or of their reception and treatment in hospital. There can be no doubt at all that the efficiency of the Metropolitan Asylums Board, as hospital and as ambulance authority, largely contributed to such measure of success as was attained in dealing with London small-pox." Passing on to review, on the one hand, the exemplary conduct of the great majority of the municipal councils, and on the other, the reprehensible behaviour of certain boards of guardians in neglecting their statutory duties, Mr. Power deals leniently with the very few among the former which, reflecting, perhaps, the antagonistic spirit of their guardian colleagues, had incurred the special censure of the Board. He nevertheless pointedly alludes to, although he forbears to name, a certain recalcitrant council which paid the penalty of disobedience by losing the services of no less than five of its own officials through their being attacked by small-pox. Although, in the exercise of his discretion, Mr. Power has deemed it inexpedient to praise municipal borough councils the preventive action of which against small-pox deserved high commendation, or, on the other hand, to hold up to reprobation individual boards of guardians which in the face of a terrible epidemic exceptionably failed in the performance of a public duty, he feels called upon to mention one vaccination authority—the board of guardians of St. Giles and St. George, Bloomsbury—the action of which was in the highest degree commendable. Under this vaccination authority very thorough measures of vaccination and re-vaccination were carried out from the first. It is the municipal borough of Holborn which profited by the services of this public-spirited board of guardians. This borough was early invaded by small-pox and there is no doubt that but for the coöperation against small-pox here happily prevailing between independent authorities jointly responsible for the repression of the disease, the rapidly growing and severe epidemic in Holborn would have attained much graver proportions.

As regards preventive measures against importation into this country of cholera and bubonic plague Mr. Power refers to the routine records of the prevalence of cholera abroad which have, as in past years, been continuously kept by members of his staff, and to the exceptional action of the Board's inspectors during the year in respect of plague. Early in 1901, on the occurrence of certain cases of locally suspected plague in districts within the outer ring of London, the Board deemed it proper to direct two of its inspectors to visit a number of the districts referred to and generally to remind the local authorities concerned of their responsibilities as well as to advise them with regard to the precautionary measures desirable to be taken beforehand in dealing with actual or suspected cases of the disease.

As regards the final section of this report, which treats of the auxiliary scientific investigations undertaken on the Board's behalf during the year, inasmuch as they do not admit of summarising we have no alternative but to refer our readers for particulars to the report before us, fully one-third of which is occupied with the highly interesting and important details contributed by Dr. Klein, Dr. Martin, Dr. M. H. Gordon, Dr. A. C. Houston, and Dr. J. S. Haldane.

MEDICINE AND THE LAW.

The Analysis of Perishable Articles of Food.

THE first prosecutions instituted by the Norfolk County Council in respect of the addition of boric acid to milk came recently to an unfortunate conclusion. In one case which was gone into fully the milk was proved by analysis to contain 22·9 grains of boric acid per imperial pint. The defendant's solicitor, however, took the point that the certificate of the public analyst was silent as to whether any change had taken place in the milk that might interfere with the analysis. The magistrates, after retiring to consider the facts and the point of law thus raised, intimated that they were satisfied as to the addition of boric acid and also that its presence in the quantities shown was such as to render the milk injurious to health. On the ground, however, that the certificate of analysis did not contain the necessary statement as to the condition of the milk when analysed the bench dismissed the summons, and three other cases in which a similar omission had been made were similarly disposed of. In a sense the point raised may be described as a technical one and the Cromer magistrates themselves so referred to it, but although it is a matter of regret that legal proceedings of importance in the interest of the public health should fail upon technical grounds, the provision to which attention was thus called is a useful one as it prevents any discussion being raised at the hearing of a summons as to the condition of the article analysed at the time of its examination and any consequent questioning of the accuracy of the certificate. The Sale of Food and Drugs Act, 1875, under which the proceedings were taken, has only one schedule and this gives the form which the certificate of the analyst should take, to which are appended brief notes, the last of which concludes with the words: "In the case of a certificate regarding milk, butter, or any article liable to decomposition, the analyst shall specially report whether any change had taken place in the constitution of the article that would interfere with the analysis." It may be observed that the summons in the case heard at Cromer was taken out under Section 3 of the Act, which enables a fine of £50 (or in the case of a repeated offence a term of imprisonment) to be imposed upon any person who shall mix with an article of food any ingredient so as to render the article injurious to health, with intent that it may be sold in that state. The prosecutions under the Sale of Food and Drugs Act with which the public and its caterers are most familiar are those under Section 6, where the offence charged is selling to the prejudice of the purchaser an article of food which is not of the nature, substance, and quality of the article demanded. The penalty under this section is limited to a fine of £20.

Is a Funnel a Chimney?

It has been decided at the Mansion House police-court that the funnel of a steam-tug emitting black smoke is a chimney within the meaning of Section 24 of the Public Health (London) Act, 1891. It was stated in court that there would be an appeal upon this question and the result should be watched with some interest by those who live near rivers that are commercial thoroughfares as well as by owners and masters of steamboats. The section in question refers to "any chimney (not being the chimney of a private dwelling-house) sending forth black smoke in such quantity as to be a nuisance," and this passage is taken without alteration from the 91st section of the Public Health Act, 1875, so that it has had an existence of many years without the question of its applicability to steam vessels being raised and decided. This, however, is no doubt accounted for by the presence of another section in the Public Health (London) [illegible] ment on board ship in [illegible] owners and others are [illegible] the present prosecution must be looked on as a legal experiment. Attention was called recently in THE LANCET[1] to the fact that smoke must be black and not brown or of any other tint according to the Public Health Acts in order to constitute a nuisance. It is curious to find in the same sentence another expression which might have been improved upon in 1891 had the sub section been considered in all its bearings instead of being adopted from the existing Act without alteration.

Registration and Vaccination.

A man named Richard Green, of Barclay-road, Walthamstow, was recently fined 20*s* and 6*s*. 6*d*. costs for giving a false address as the place of birth of his child when registering it. This was done in order to avoid vaccination. It is not an uncommon device but it is one which gives some trouble to the vaccination officer who in the performance of his duty has to trace out the case. It is a trick, moreover, which deserves severe punishment not only in view of the difficulty which it imposes upon the proper carrying out of the law as to vaccination but because for other reasons the accurate registration of births is of importance to the public and to the infants registered.

Carbolic Acid as a Poison.

Carbolic acid is frequently used as a means of committing suicide and it also is the cause of death in a great many instances in which it is taken accidentally. The gross carelessness with which it is treated by persons who should be sufficiently well-informed to guard against such mishaps is shown at the inquests which follow in fatal cases. At one of these held recently at Derby upon the body of a man who had been the holder of an off-licence for the sale of alcoholic liquors it was proved that the deceased was in the habit of taking certain medicine which had been prescribed for him by drinking it out of the bottle in the dark without any measurement of the quantity taken. He kept the bottle of medicine on a shelf in his bedroom side by side with two other bottles, one of which contained port wine and the other carbolic acid. One night he drank carbolic acid instead of his medicine and died. It is not easy to protect the lives of persons so reckless.

ASYLUM REPORTS.

Monmouthshire Asylum, Abergavenny (Annual Report for 1902).—The average number of patients resident during the year was 1105, comprising 543 males and 562 females. The admissions during the year amounted to 247—viz., 127 males and 120 females. Of these 207 were first admissions. Dr. J. Glendinning, the medical superintendent, states in his report that the ordinary admissions were the highest in any year since the opening of the asylum and were 23 in excess of those admitted during 1901 and 27 more than the average annual admissions during the previous ten years. Many of these patients were very much enfeebled and debilitated. The principal causes of mental disorder among the admissions were bodily disease and debility in 60 cases, intemperance in drink in 34 cases, and hereditary predisposition to insanity in 47 cases. The number of patients in the asylum on Dec 31st was 1111, "and as the statutory accommodation in the asylum is for 1077 patients there has been considerable overcrowding both in the male and female divisions." This overcrowding will necessitate the removal of patients from the counties of Brecon and Radnor to the new asylum at Talgarth. The number of patients discharged as recovered during the year amounted to 102—viz., 51 males and 51 females—or 9·2 per cent. of the average number resident. The deaths during the year amounted to 112, or 10·1 per cent. as calculated on the same basis. Of the deaths two were due to senile decay, four to epilepsy, six to renal disease, eight to pneumonia, 12 to pulmonary tuberculosis, 14 to cerebral softening, 15 to general paralysis of the insane, 28 to cardiac disease, and the rest to other causes. The Commissioners in Lunacy state in their report that the general condition of the asylum was very good, that the patients were suitably lodged with due regard to safety and comfort, that the dormitories were in [illegible] bedding was scrupulously clean, that [illegible] to be satisfactory [illegible] and personal neatness was eminently satisfactory, and that the medical case-books and records were well kept, the former being illustrated with excellent photographs. The committee of management states in its report that part of the "Maindiff Estate," together with a good range of farm buildings and cottages standing thereon, was purchased for the sum of £9649, the extent of ground occupying 82 acres. Various improvements have also been effected in the farm, in the boiler-house, and in the stores.

Suffolk County Asylum (Annual Report for 1902).—The average number of patients resident during the year was 582, comprising 257 males and 325 females. The number of patients admitted during the year was 214—viz, 103 males and 111 females. Of these, 175 were first admissions. Dr. James R. Whitwell, the medical superintendent, states in his report that there was an increase in the gross admissions for the year of 45 as compared with the previous year and that this increase was very largely made up of new cases. Although the majority of patients admitted were in fair bodily condition "over 30 per cent. were in an enfeebled and exhausted condition, mostly owing to the fact that they were not brought under treatment sufficiently early." The number of patients discharged as recovered during the year amounted to 66—viz., 42 males and 24 females, or 11·3 per cent. of the average number resident. The deaths during the year amounted to 79—viz, 27 males and 52 females, or 13·6 per cent. as calculated on the same basis. Of the deaths three each were due to epilepsy and enteric fever, four to renal disease, 12 each to cardiac disease and general paralysis of the insane, 12 to pulmonary and other forms of tuberculosis, 18 to senile decay, and the rest to other causes. Post-mortem examination was made in every case of death except one. The casualties during the year were few and of no serious character. One patient was discharged within a short time of admission as an analysis of his case showed that he was suffering from deaf-mutism only. The average weekly cost of maintenance during the year has risen from 10*s.* 6¾*d.* to 11*s.* 1½*d.*, of which 5¾*d.* is due entirely to outside causes—namely, local rates. "This increase is one largely due to a multiplicity of causes inseparable from the transition stages of heating and lighting and to the condition of boarding out [patients] in other counties. ...... It is hoped that as our new buildings gradually become occupied the cost of maintenance will gradually resume a normal figure." The institution as a whole has been lighted with electricity since December, 1901, and it appears to be a safer, healthier, and more economical method of lighting than that which has hitherto been used. "The average annual increase of patients admitted to the asylum is, roughly speaking, about 11 and shows no sign of diminishing. ...... An actual increase of mental disease can be shown to exist out of proportion even to the population." The Commissioners in Lunacy state in their report that the wards of the asylum were found to be in excellent order, that the patients were very orderly and generally contented and in a satisfactory condition as regards dress and personal neatness, and that the medical case-books and post-mortem records were carefully and well kept. The committee of management states in its report that the whole asylum is now lighted with electricity and that fire alarms and telephones have been fixed throughout the building. The water-supply is excellent and the sewage works have proved themselves efficient.

Looking Back.

FROM

THE LANCET, *SATURDAY*, OCT. 15, 1825.

CAUTION TO PSALM SINGERS.

Dr. BLUNDELL, adverting, in his physiological lecture on Monday last, to the comparative anatomy of the maxillary joint in predaceous, and herbivorous animals, observed, in this respect, that man resembled the herbivorous class; but there was a greater extent of motion in the human jaw, and consequently a greater liability to dislocation. The learned lecturer mentioned a curious case in illustration of this fact. A devout person, of the Wesleyan persuasion, lifting up his voice in a hymn to its highest pitch, brought the condyloid process to the very edge of the glenoid cavity, and, attempting a shake at this critical moment, actually dislocated his jaw. We hasten to give publicity to this fact, that psalm-singers may not in future attempt to shake with their condyloid processes at the edge of their glenoid cavities. We may add too, that although psalm-singing is unquestionably one of the purposes for which jaws were given to man, yet their peculiar structure renders it doubtful whether the great Author of nature would not prefer a more moderate exercise of this function, than devout vocalists are wont to indulge in.

Bite of the Tarantula.

"There was a time when physicians believed that the bite of the tarantula destroyed sensation and life, and that the only remedies which could avert this fatal result were music and dancing. It was religiously believed at the time, that persons bitten by this insect evinced an invincible aversion to the colours of black and blue, while at the same time they manifested a decided predilection for white, red, and green. There were some who even went so far as to affirm that they had seen tarantulas dance in cadence to the patients, and there was no sort of absurdity broached by the people on this subject for which physiologists did not attempt to account. MEAD thought the poison acted directly on the blood, GEOFFREY on the nerves, and both these physicians, as well as GRUBE and SHUCHZER, were only followers, in this respect, of the celebrated BAGLIVI, who was a zealous supporter of these errors. The extravagance of the imposture operated as a cure for credulity. The courage of Dr. SANGINETTI, who caused himself to be bitten by tarantulas at the hottest period of the summer, without experiencing any serious inconvenience, and the excellent work of SERAO completely destroyed the romances to which physicians of the highest reputation had for three centuries given credit; and the malady was regarded only as a sort of hypochondriacal affection, to which the reapers are subject under the burning influence of the sun, in the vicinity of Tarentum. This last opinion which is now generally adopted, does not seem to accord with the case given by Dr. MAZZOLANI, and the attention of the physicians, who have opportunities of observing the effects of the bite of the tarantula may still be profitably directed to this subject."[1]

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN 76 of the largest English towns 8154 births and 4554 deaths were registered during the week ending Oct. 10th. The annual rate of mortality in these towns, which had been 16·5, 16·3, and 15 3 per 1000 in the three preceding weeks, rose again last week to 15·8 per 1000. In London the death-rate was 14·5 per 1000, while it averaged 16·3 per 1000 in the 75 other large towns. The lowest death-rates in these towns were 4 7 in Hornsey, 9·1 in Handsworth, 9·6 in Croydon, 9·9 in Hanley, 10 4 in Reading, 10·5 in Derby, 10·6 in King's Norton, 10·9 in West Hartlepool, and 11·2 in Leyton; while the highest rates were 20·2 in Stockport, 20 3 in St. Helens, 20·4 in Merthyr Tydfil, 21·1 in Newcastle-on-Tyne, 21 2 in Ipswich and in West Bromwich, 21·4 in Middlesbrough, 22 8 in Rotherham, 23·4 in Sunderland, and 24·0 in Bootle. The 4554 deaths in these towns last week included 707 which were referred to the principal infectious diseases, against 918, 752, and 697 in the three preceding weeks; of these 707 deaths, 490 resulted from diarrhœa, 46 from whooping-cough, 45 from diphtheria, 45 from "fever" (principally enteric), 42 from scarlet fever, 34 from measles, and five from small-pox. No death from any of these diseases was registered last week in Hornsey, Reading, Burton-on-Trent, Handsworth, Barrow-in-Furness, Halifax, or West Hartlepool; while they caused the highest death-rates in West Ham, Wolverhampton, Warrington, Burnley, Preston, Middlesbrough, Sunderland, and Merthyr Tydfil. The greatest proportional mortality from measles occurred in Warrington, Bury, and Sunderland; from scarlet fever in Wolverhampton and Merthyr Tydfil; from diphtheria in Ipswich; from whooping-cough in Middlesbrough; from "fever" in St. Helens and Merthyr Tydfil; and from diarrhœa in West Ham, Wolverhampton, West Bromwich, Birmingham, Coventry, Warrington, Burnley, Preston, Rotherham, Middlesbrough, and Gateshead. Of the five fatal cases of small-pox registered in these towns last week two belonged to Bolton and one each to Leicester, Salford, and York. The Metropolitan Asylums hospitals contained 17 small-pox cases on Saturday last, Oct. 10th, against 41, 29, and 21 at the end of the three preceding weeks; two new cases were admitted during the week, against seven, one, and one in the three preceding weeks. The number of scarlet fever patients in these hospitals and in the London Fever Hospital, which had been 1803, 1886, and 1877 at the end of the three preceding weeks, had risen again to 1881 at the end of last week; 240 new cases were admitted during the week, against 261, 293, and 235 in the three preceding weeks. The deaths referred to diseases of the respiratory organs in London, which had been 128, 134, and 161 in the three preceding weeks, declined again to 146 last week, and were 21 below the number in the corresponding period of last year. The causes of 42, or 0·9 per cent., of the deaths in the 76 towns last week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Bristol, Leicester, Nottingham, Salford, Newcastle-on-Tyne, and in 47 other smaller towns; the largest proportions of uncertified deaths were registered in Liverpool, Bootle, Sheffield, Hull, and South Shields.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in eight of the principal

---

[1] Observations by M. Magliari, the editor of the *Osservatore Medico*, on a case published in that journal by Dr. Francesco Mazzolani of Naples. The patient was Giovanni Battista Petrini, a young Tuscan, about 15 years old, who was bitten on the second toe of the left foot while sleeping in the open fields at harvest time.

Scotch towns, which had been 16 1, 16 8 and 17 3 per 1000 in the three preceding weeks, declined again to 16 0 per 1000 during the week ending Oct 10th, but was 0 2 per 1000 in excess of the mean rate during the same period in the 76 large English towns The rates in the eight Scotch towns ranged from 9·3 in Perth and 14 2 in Aberdeen, to 18 0 in Greenock and 19 8 in Dundee The 525 deaths in these towns included 41 which were referred to diarrhœa, nine to "fever," eight to measles, six to whooping cough, four to scarlet fever, and three to diphtheria, but not one to small pox In all, 71 deaths resulted from these principal infectious diseases last week, against 51, 77, and 65 in the three preceding weeks These 71 deaths were equal to an annual rate of 2 2 per 1000, which was 0 2 per 1000 below the mean rate last week from the same diseases in the 76 large English towns The fatal cases of diarrhœa, which had been 44 and 42 in the two preceding weeks, further declined last week to 41 of which 21 occurred in Glasgow, ten in Dundee, three in Aberdeen, three in Greenock, and two in Edinburgh The deaths referred to different forms of "fever," which had been five, seven, and six in the three preceding weeks, rose again to nine last week and included five in Glasgow and three in Dundee. The fatal cases of measles, which had been eight, five, and four in the three preceding weeks, increased again last week to eight, all of which were registered in Glasgow The deaths from whooping cough, which had been ten, nine, and seven in the three preceding weeks, further declined to six last week and included three in Glasgow The fatal cases of scarlet fever, which had been three, four, and two in the three preceding weeks, rose again last week to four, of which two occurred in Glasgow The deaths referred to diseases of the respiratory organs in these towns, which had been 71, 84, and 88 in the three preceding weeks, declined again last week to 62 and showed a decline of 44 from the number in the corresponding period of last year The causes of 11 or more than 2 per cent, of the deaths registered in these eight towns last week were not certified

HEALTH OF DUBLIN

The death rate in Dublin, which had been 19 5 21 7, and 18 3 per 1000 in the three preceding weeks, rose again to 19 7 per 1000 during the week ending Oct 10th During the past four weeks the death rate has averaged 19 8 per 1000 the rates during the same period being 15 0 in London and 16 8 in Edinburgh The 143 deaths of persons belonging to Dublin registered during the week under notice were ten in excess of the number in the preceding week and included nine which were referred to the principal infectious diseases, against 17, 16 and five in the three preceding weeks, of these four resulted from diarrhœa two from whooping cough, one from scarlet fever, one from diphtheria and one from "fever" but not any from either small pox or measles These nine deaths were equal to an annual rate of 1 2 per 1000 the death rates last week from the principal infectious diseases being 2 1 in London and 1 0 in Edinburgh The fatal cases of diarrhœa, which had been five, 14, and three in the three preceding weeks, rose again last week to four The 143 deaths in Dublin last week included 32 of children under one year of age and 29 of persons aged 60 years and upwards, the deaths both of infants and of elderly persons showed a slight decline from the respective numbers recorded in the preceding week One death from violence and seven inquest cases were registered, and 64, or nearly 45 per cent, of the deaths occurred in public institutions The causes of five or nearly 4 per cent., of the deaths registered in Dublin last week were not certified

VITAL STATISTICS OF LONDON DURING SEPTEMBER 1903.

In the accompanying table will be found summarised complete statistics relating to sickness and mortality in the City of London and in each of the metropolitan boroughs With regard to the notified cases of infectious diseases it appears that the number of persons reported to be suffering from one or other of the nine diseases specified in the table was equal to an annual rate of 6 5 per 1000 of the population, estimated at 4,613 812 persons in the middle of the year In the three preceding months the rates had been 6 0, 6 4, and 5 5 per 1000 respectively The rates were considerably below the average in Kensington, Chelsea, the City of Westminster, Hampstead, Stoke Newington, Holborn, and the City of London, while they showed the largest excess in St Marylebone, Ha [illegible] Stepney, and Deptford [illegible] a further marked decrease from that recorded during recent months, of the 27 cases notified during September, 15 belonged to Lambeth, four to St Pancras, two to Battersea, and one each to [illegible] minster St. Marylebone, [illegible] The Metropolitan Asylums [illegible] patients at the end of last month, against 57, 66, and 57 at the end of the three preceding months, the weekly admissions averaged five last month, against 12, 15, and nine in the three preceding months Scarlet fever was rather more prevalent during September than it had been in the preceding month, the greatest proportional prevalence of this disease occurred in Finsbury, Bethnal Green, Stepney, Poplar, and Deptford The number of scarlet fever patients in the Metropolitan Asylums hospitals, which had been 1614, 1697, and 1754 at the end of the three preceding months, had further risen to 1849 at the end of last month, the weekly admissions averaged 241, against 195 234 and 211 in the three preceding months The prevalence of diphtheria showed a considerable excess over that recorded during August. Among the various metropolitan boroughs this disease was proportionally most prevalent in St Marylebone Hackney, Poplar, Deptford, and Greenwich There were 671 diphtheria patients under treatment in the Metropolitan Asylums hospitals at the end of last month, against 781, 840 and 716 at the end of the three preceding months, the weekly admissions during September averaged 114, against 119, 130, and 114 in the three preceding months The prevalence of enteric fever, which had shown a continued rise during the preceding five months, further increased last month; the greatest proportional prevalence of this disease was recorded in Stoke Newington, Hackney, Shoreditch, Stepney, and Bermondsey The number of enteric fever patients under treatment in the Metropolitan Asylums hospitals, which had been 88, 119 and 172 at the end of the three preceding months, had further risen to 247 at the end of last month, the weekly admissions averaged 40 against 17, 18 and 27 in the three preceding months Erysipelas was proportionally most prevalent in Kensington, Holborn, Shoreditch, Bethnal Green Southwark, and Bermondsey The 20 cases of puerperal fever notified last month included three in Paddington three in Southwark, two in Hammersmith, two in Fulham two in Hackney, two in Stepney, and two in Lambeth

The mortality statistics in the table relate to the deaths of persons actually belonging to the various boroughs, the deaths occurring in public institutions having been distributed among the boroughs in which the deceased persons had previously resided During the five weeks ending Oct 3rd the deaths of 6380 persons belonging to London were registered, equal to an annual rate of 14 4 per 1000 The lowest death rates in London last month were 10 0 in Hampstead 10 2 in Stoke Newington 10 8 in Hammersmith, 11 2 in Wandsworth 11 7 in the City of Westminster, and 12 3 in Lewisham, while the highest rates were 18 1 in Shoreditch, 18 4 in Southwark, 18 9 in Stepney 19 2 in Poplar, 19 5 in Finsbury, and 19 8 in Bethnal Green. The 6380 deaths from all causes included 1163 which were referred to the principal infectious diseases, of these three resulted from small pox, 54 from measles 26 from scarlet fever, 56 from diphtheria 77 from whooping cough 38 from enteric fever, and 909 from diarrhœa The lowest death rates last month from these infectious diseases were recorded in Chelsea the City of Westminster, Hampstead, Stoke Newington, Holborn and the City of London, and the highest rates in Fulham, Shoreditch Bethnal Green, Stepney Poplar, and Southwark The three fatal cases of small pox included two in Lambeth and one in the City of Westminster The 54 deaths from measles were 40 below the corrected average number, among the various metropolitan boroughs this disease was proportionally most fatal in Fulham, St Marylebone Stepney, Lambeth and Camberwell The 26 fatal cases of scarlet fever showed a decline of 46 from the average number in the corresponding periods of the ten preceding years, the greatest proportional mortality from this disease occurred in Paddington, Islington, Bethnal Green, Poplar, and Bermondsey The deaths from diphtheria, which had averaged 198 in the corresponding

* Including membranous croup.

periods of the ten preceding years, numbered only 56 last month; among the various metropolitan boroughs this disease was proportionally most fatal in Paddington, St. Marylebone, Hackney, Bethnal Green, Stepney, and Poplar. The 77 fatal cases of whooping-cough were 68 below the corrected average number; the greatest proportional mortality from this disease was recorded in Holborn, Finsbury, Stepney, Battersea, and Deptford. The 38 deaths from enteric fever were exactly one-half of the average number in the corresponding periods of the ten preceding years; among the various metropolitan boroughs the highest "fever" death rates were registered in Kensington, St. Pancras, Hackney, Shoreditch, Stepney, and Lewisham. The 909 fatal cases of diarrhœa were slightly in excess of the corrected average number; this disease was proportionally most fatal in Fulham, Shoreditch, Bethnal Green, Stepney, Poplar, and Southwark. In conclusion, it may be stated that the aggregate mortality in London last month from these principal infectious diseases was more than 21 per cent. above the average.

Infant mortality in London during September, measured by the proportion of deaths among children under one year of age to registered births, was equal to 166 per 1000. The lowest rates of infant mortality were recorded in St. Marylebone, Hampstead, Holborn, the City of London, and Lewisham; and the highest rates in Kensington, Shoreditch, Bethnal Green, Poplar, Southwark, and Bermondsey.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

THE following appointments are notified:—Staff Surgeon N. L. Richards to the *Barrosa* (dated Oct. 20th). Fleet Surgeons: W. Eames to Plymouth Hospital and A. L. Christie to the *Mars* (dated Oct. 12th). Surgeon L. S. Whitwam to the *Caledonia* (dated Oct. 12th).

ROYAL NAVAL VOLUNTEER RESERVE.

Sir Frederick Treves, Bart., K.C.V.O., C.B., to be Honorary Staff Surgeon (dated Oct. 6th, 1903) and Dr. Francis John Hannan to be Surgeon (dated Oct. 6th, 1903).

ROYAL ARMY MEDICAL CORPS.

Lieutenant-Colonel Richard G. Thomsett retires on retired pay (dated Oct. 14th, 1903); Lieutenant J. T. K. Thomson, Glasgow Companies, Royal Army Medical Corps (Volunteers) to be Surgeon-Lieutenant (dated Oct. 14th, 1903).

T[illegible] officers proceed to England in [illegible]ops on homeward voyage as follows:—*Soudan*, Oct. 14th: Lieutenant-Colonel Emerson (in charge), Lieutenant-Colonel Stuart, Major Moore, Major Adamson, Captain Moore, and Captain Harrison *Plassey*, Oct. 24th: Major Fayrer, Major Boles, Captain Smith, Captain Grattan, Captain Campbell, and Captain Hayes. *Sicilia*, Nov. 4th: Lieutenant-Colonel Battersby (in charge), Lieutenant-Colonel Tyrell, Major Hennessy, Major Jackson, Captain Forrest, and Captain Warning. *Assaye*, Nov. 13th: Lieutenant-Colonel Mulvany (in charge), Lieutenant Colonel Dugdale, Major Norris, Major Nash, Major Windle, Captain Bliss, Captain Riddick, Captain Swabey, and Captain Hopkins. *Soudan*, Dec. 23rd: Lieutenant-Colonel Jones (in charge), Major Maher, Major Cocks, Major Hore, Captain MacDougall, and Captain Clements. *Plassey*, Jan. 1st: Lieutenant-Colonel Allfort (in charge), Lieutenant Colonel Thomson, Major Macdonald, Major Inniss, Major Forde, Captain Cockrane, Captain Morris, and Captain Marriott. *Sicilia*, Jan. 8th: Lieutenant-Colonel Seymour (in charge), Lieutenant-Colonel Cowen, Major Green, Major Maturin, Major Young, and Captain Huddleston. *Assaye, viâ* Cape, Feb. 16th: Lieutenant-Colonel Johnston (in charge), Lieutenant-Colonel White, Major Watson, Major Davoren, Captain Brogden, Captain McCarthy, Captain Bowen, and Captain Young. *Soudan*, Feb. 26th: Lieutenant-Colonel Maclean (in charge), Lieutenant-Colonel Carey, Major Cardozo, Major Cree, Major Griffiths, and Captain Collingwood. *Plassey*, March 8th: Lieutenant-Colonel Geoghegan (in charge), Lieutenant-Colonel Carmichael, Major Thompson, Major O'Donnell, Major Bullen, Captain Martin, Captain O'Grady, Captain Carter, and Captain Hall. *Sicilia*, April 7th: Lieutenant-Colonel Birrell (in charge), Major Weir, Major Power, Major Wright, Captain Carroll, and Captain Macpherson.

Captain E. Brodribb, from half-pay, to be Captain, with precedence next below G. M. Goldsmith (dated Sept. 21st, 1903).

The name of Lieutenant (on probation) Osborne Ievers is as now described and not as stated in the *Gazette* of Sept. 18th, 1903.

ROYAL ARMY MEDICAL CORPS (MILITIA).

Lieutenant J. W. Hopkins is seconded for service under the Foreign Office (dated Sept. 29th, 1903).

VOLUNTEER CORPS.

Royal Garrison Artillery (Volunteers): 1st Sussex: Surgeon-Lieutenant F. Loud resigns his commission and is appointed Captain (dated Oct. 10th, 1903) *Rifle*: 1st Volunteer Battalion the East Yorkshire Regiment: Arthur Tinsley Sissons to be Surgeon-Lieutenant and to be borne as Supernumerary whilst doing duty with the Yorkshire Volunteer Infantry Brigade Bearer Company (dated April 4th, 1903).

VOLUNTEER INFANTRY BRIGADE BEARER COMPANIES.

Yorkshire: The appointment of Arthur Tinsley Sissons, which was announced in the *London Gazette* of April 3rd, 1903, is cancelled.

WAR OFFICE CHANGES.

The recent changes which have been made in the *personnel* of the War Office, besides being a matter of national interest, directly concern the army as a whole and with it army medical administration. The disclosures of the late War Commission have naturally aroused a strong feeling of indignant surprise not altogether unmixed with alarm. Whether the new appointment of Mr Arnold Forster as War Minister and of Mr. Bromley-Davenport as Financial Secretary to the War Office will be followed or not by those radical reforms that are called for remains to be seen. But Mr. Arnold-Forster has played a conspicuous part as an army critic and reformer and he will now have an opportunity of giving effect to some of those drastic changes of which he has so long been an advocate. What is obviously wanted at the War Office at the present time is a strong man but not a strong party man. As regards Mr. Brodrick it may be safely said that he undertook the most difficult task that could fall to the lot of any Minister at the time when he became the head of the War Office. As far as the medical service, at any rate, is concerned, it must be admitted that he has made very strenuous exertions to render it efficient.

Major M. T. Yarr, R.A.M.C., will, it is said, be appointed medical officer on the staff of Lord Lamington, the new Governor of Bombay. Major Yarr has given a great deal of time and attention to the study of ophthalmology and his services to the army as an expert in this direction have been of much value.

HOSPITAL ACCOMMODATION AT DEOLALI.

The proposals for additional hospital accommodation at Deolali, says the *Pioneer Mail*, are being considerably reduced in view of the fact that in the near future a hospital train from stations in the Punjab and Bengal commands will be available and will doubtless be able to run through to Bombay, so as to deliver sick soldiers direct on board the ships without stopping at Deolali. There is also the fact that a hospital ship will probably be despatched from Bombay on three separate trips to England with 100 invalids each time, thus reducing the number of sick proceeding by ordinary troopship.

HOSPITAL EQUIPMENT FOR THE ARMY IN INDIA.

The *Pioneer Mail* of Sept. 18th states that a comprehensive scheme is now being worked out for revising the equipment of general hospitals, field hospital store depôts, and base hospital store depôts in the army in India.

NAVAL MEDICAL SUPPLEMENTAL FUND.

At the quarterly meeting of the directors of the Naval Medical Supplemental Fund, held on Oct. 13th, Sir J. N. Dick, K.C.B., R N (retired), being in the chair, the sum of £45 was distributed among the several applicants.

The special corps dinner of the Royal Army Medical Corps is to be held on Oct. 21st at the Whitehall Rooms, Hôtel Metropole. Officers who have not yet notified their intention of being present are requested to do so without delay to the honorary secretary.

"Audi alteram partem."

THE LUNG REFLEX OF ABRAMS.

To the Editors of THE LANCET.

SIRS,—The letter of Dr. Albert Abrams in THE LANCET of Oct. 10th, p. 1032, in which a recent annotation of your own[1] on the Cardiac Reflex of Abrams is supplemented by certain valuable observations, has prompted me to offer a few remarks on a kindred phenomenon which also bears the name of the same distinguished observer—viz., the lung reflex of Abrams.

There can, I think, be no doubt that notwithstanding the striking character of the work on this subject by the American physician and its signal importance in connexion with the diagnosis, the prognosis, and the treatment of many pulmonary conditions, it is but little known to the practitioners of our own country. I may add that for at least a year I have followed the practice of Abrams in eliciting the lung reflex on my patients and I am fully convinced of its value. There are two such reflexes: a reflex of dilatation and a reflex of contraction. In clinical work the former is the more important and generally useful. Briefly put, it consists in the fact that the lung has an *inherent* power of dilating, apart from the breathing forces or atmospheric pressure and this inherent capacity of dilatation can be readily evoked by simple stimuli applied either to the chest wall or to the interior of the nares.

Now it is evident that this inherent or essential expansibility of the lung is no newly propounded phenomenon. It was indeed affirmed long ago by Laennec who adduced many and ingenious facts, both physiological and clinical, to prove it. In his chapter on Spasmodic Asthma he remarks: "The study of respiration by means of auscultation furnishes us, both in health and disease, with still more numerous phenomena which leave no room to doubt that the lungs possess an inherent power of action, independently of the other powers of inspiration and expiration. ...... In regard to expansion its mechanism is so little understood that physiologists have been forced to admit in order to explain it a vital property under the name of *expansibility* or *expansile power*. Without investigating the probabilities of this theory, I shall here content myself with inquiring, as a matter of fact, whether the lungs are capable of an active expansion independently of that which they undergo from the effects of atmospheric pressure in following the dilatation of the walls of the chest during inspiration."[2] Such is the phenomenon which he goes on to prove. It was not, however, until recent years that anything like a satisfactory demonstration of the presence of broncho-dilator as well as broncho-constrictor fibres in the vagus was made by Roy and Brown and during the present year this seems to have been conclusively established by the work of Dixon and Brodie.[3] But it undoubtedly stands to the credit of Abrams to have proved at least seven years since by a simple clinical observation that the vagus must contain broncho-dilator as well as broncho-constrictor fibres.

Such an observation may be easily carried out as follows. The patient, stripped to the waist, is directed to lie on his back and after he has rested a few minutes and the breathing becomes as easy as possible the right edge of the superficial cardiac dulness is percussed out and marked with a dermograph. In like manner the upper and left edges of the superficial dulness are determined. The front of the chest is then briskly rubbed with a towel for a minute until a red glow is produced. On percussion now being made it will be found (normally) that the pulmonary resonance extends a considerable distance inwards beyond the dermographic lines. After waiting for from two to three minutes longer, the extension of resonance will have disappeared and the dulness will be restored to its original area. A similar phenomenon may be elicited at the basal borders of the lung. I have found in practice (although Abrams gives no instructions on the point) that the recumbent posture is the best, favouring as it does a restful position of the organs.

This reflex dilatation of the lung is due to the action of broncho-dilator fibres in the vagus, but when friction is made over the cardiac area also the dilatation is assisted by a simultaneous inhibition of the heart which causes a diminution in the amount of blood in the pulmonary capillaries. It was proved in the experiments of Dixon and Brodie that such a diminution causes increased distensibility of the lung.

The lung reflex of dilatation can also be produced by the inhalation of irritant vapours, such as ammonia, by plugging the nares with cotton-wool, and by vigorous percussion over the epigastrium. It would appear, however, that irritants commonly acting in the nose may produce either the lung reflex of dilatation or that of contraction, according as the irritant selects the broncho-dilator or the broncho-constrictor fibres of the vagus. Many cases of asthma are due to such irritation of the broncho-constrictors and it seems likely that certain purely emphysematous conditions are produced contrariwise. In either case the application of cocaine to the nasal cavities inhibits the phenomenon. In the experiments of Dixon and Brodie already referred to curious discrepancies were often obtained in different animals. Thus in the dog and rabbit direct vagal stimulation produced bronchiolar constriction, whereas in the cat it usually produced dilatation which lasted all the time the stimulus was applied, though many variations were found in the latter animal, such as an initial rapid constriction or first a relaxation and then a constriction.

Abrams has also shown that there normally exists in the lung certain areas more or less "atelectatic" in character. Such areas are specially marked just by the breast-bone beneath the clavicles and towards the angles of the scapulæ. These can be dispelled by repeated deep inspirations. A blow struck near the manubrium increases the atelectatic area there by causing the lung reflex of contraction, while the atelectasis so produced is immediately dispelled by a blow struck over the epigastrium. If the skin be previously irritated over the part or the nasal mucosa be cocained this reflex of contraction cannot be produced.

Sufficient has been said to show that in these reflexes we possess valuable clues to diagnosis and treatment. I have already made a considerable number of observations in which much light was shed on the state of the lungs by testing their response either in whole or in part to the normal reflexes and I believe that these reflexes ought to be tested as a matter of routine in the investigation of pulmonary and cardiac diseases, just as the reflexes are tested in the investigation of diseases of the nervous system. As regards treatment they yield beyond doubt a scientific basis for the practice of counter-irritation. A counter irritant applied to any part of the chest wall not only induces but maintains a pulmonary dilatation underneath. The relief afforded in cases of bronchitis, pulmonary collapse, &c., by such topical means is thus (at least partially) explained. It has been shown by Abrams that hot poultices continuously applied over the broncho pneumonic lungs of children are the best means of counteracting the condition of collapse which is commonly set up. Again, the intranasal treatment of cases of asthma and emphysema may be clearly indicated by the reflexes which are excited; generally speaking, the application of cocaine temporarily tending to dispel either reflex. In like manner in regard to inhalations the reflex of contraction is dispelled by such agents as ether and chloroform, while that of dilatation is dispelled by nitrite of amyl.

I am, Sirs, yours faithfully,

Henrietta-street, W., Oct. 10th, 1903. A. G. AULD.

THE VISION OF MYOPES.

To the Editors of THE LANCET.

SIRS,—It is often interesting to note the little devices by which patients try to overcome their disabilities. In this way we may sometimes get unexpected information. It is well known that myopes can improve their vision by partially closing the eyelids and that this improvement arises from the cutting off of the circles of diffusion; indeed, the word myopia is, of course, derived from two Greek words signifying to shut the eye. "Many myopes have so very much accustomed themselves to approximate the eyelids that it actually belongs to their physiognomy, and they persevere in doing so, even when the use of concave spectacles makes it superfluous," says Donders. I was under the impression that the best method a myope of low degree could adopt to see more clearly at a distance without the aid of any optical contrivance was partially to close the eyelids. A patient some years ago taught me a method that was new to me and of which I have not yet seen an account. A boy, aged 17 years, with myopia of one and a half dioptres, showed me that he could greatly improve his distant vision by putting his finger on the external canthus of one eye and drawing the eyelids outwards. This observation I have confirmed on myself and others. If a + 2 D. spherical glass be put before an emmetropic eye so as to render it myopic, it will be found that the large letters of Snellen's types can be read at five metres much better by drawing out the upper eyelid by the finger than by approximating the eyelids in the ordinary way by the action of the orbicularis. The difference between the two methods is considerable; by the one vision equal to $\frac{5}{36}$ can barely be reached, by the other one can succeed after a [illegible] vision up to $\frac{5}{18}$ or even higher. [illegible] tion one can easily see that t[illegible] letters became more distinct when approximating the eyelids, and that both horizontal and vertical strokes, especially the latter, became plainer when the upper eyelid was stretched by the finger. This result was to me quite unexpected. One might perhaps have thought that the circles of diffusion could be cut off as well by one method as the other. A little experiment will, however, show at once the superiority of the method of drawing out the upper eyelid by the finger.

I am, Sirs, yours faithfully,
E. DONALDSON, B.A. T.C.D., L.R.C.S. Irel.
Londonderry, Oct. 10th, 1903.

PUBLIC VACCINATORS IN RURAL DISTRICTS.

To the Editors of THE LANCET.

SIRS,—As I am appointed to give evidence before the departmental commission of the Local Government Board on behalf of the public vaccinators in rural districts of England and Wales I should be glad to receive from those gentlemen information giving instances of excessive distances and any accurate statistics of the proportion of visits paid to the number of vaccinations effected. In all cases the various fees allowed to each vaccinator should be given. Correspondence may be addressed to me direct and must reach me within the next two weeks.

I am, Sirs, yours faithfully,
A. MAUDE.
Winterton House, Westerham, Kent, Oct. 12th, 1903.

THE M.D. DEGREE OF BRUSSELS.

To the Editors of THE LANCET.

SIRS,—In THE LANCET of Oct. 10th Dr. N. Leonard gives a clear account of the general requirements of the M.D. Brux. examination but has surely omitted to state a fact which is generally not known and which detracts considerably from the value and status of the degree. That fact is that the M.D. Brux. confers no right to practise in Belgium, as it is not a "State University" examination and that it is therefore practically valueless from a legal point of view. The Belgians themselves take the "State degree," which is quite another matter.—I am, Sirs, yours faithfully,

P. A. NIGHTINGALE, M.D. Edin.
Ludgate-hill, E.C., Oct. 10th, 1903.

To the Editors of THE LANCET.

SIRS,—I have read with interest your annotation[1] on the M.D. degree of Brussels. I have thought for many years that those who have received their medical education in London have a most distinct grievance against the University of London. May I quote my own case. Before the age of 17 I matriculated at the University and within a month or two of joining a London medical school I passed the preliminary scientific examination. I then found that to pass the intermediate examination I should have to acquire an intimate knowledge of inorganic chemistry, a subject of which I knew little or nothing and for which I had no particular aptitude.

I found, moreover, that the time I should necessarily have to spend in acquiring this special knowledge would lose me my position among my contemporaries and my right to compete for certain prizes. In the circumstances I abandoned the London degree altogether. After all but ten years of practice I can conscientiously say that on no single occasion I can recall would such knowledge of inorganic chemistry as the University requires have been of the slightest use to me. I am, Sirs, yours faithfully,

Oct. 11th, 1903. F.R.C.S. ENG.

FEVER AND CONVULSIONS DUE TO ASCARIDES.

To the Editors of THE LANCET.

SIRS,—In regard to your recent annotation upon the above subject[1] and the subsequent correspondence thereon, may I point out that, owing to the almost universal presence of these parasites amongst the natives of India, this is a matter which has already received the careful attention of officers of the Indian Medical Service. One of the commonest causes of slight attacks of fever in that country is the presence of ascarides and, further, the most extraordinary and misleading symptoms are undoubtedly due to the presence in excessive numbers of this worm or to the wonderful journeys undertaken by this enterprising animal. If your readers will consult the writings of the late Norman Chevers or the files of the *Indian Annals of Medicine*, *Madras Quarterly Journal of Medical Science*, *Indian Medical Gazette*, &c., as well as the Transactions of the S. I. Branch of the British Medical Association they will find how thoroughly the matter has been investigated in that country. I myself believe that there is no room for doubt that this parasite is capable, by continued pressure, of forcing a passage through various tissues. *Per contra*, I do not believe in the "toxin" theory, which, by the way, is much older than the article by Dr. Wettendorff referred to in the original note.

The foregoing affords another instance of what is an undoubted fact—viz., that a large number of what are still regarded as being moot or as being fresh points, especially in "tropical" medicine, have long ago been investigated, discussed, and settled in India, as a careful study of the medical literature of that country, including many scarce and unattractive-looking "reports," made clear to me some years ago. So, also, as regards treatment, one too often sees methods or medicines recommended as original which have years before been tried and adopted or rejected in India. I had collected many examples of this kind of error with a view to ultimate publication, but for several reasons, of which ill health is perhaps the most effective, I cannot expect to accomplish that which I had planned. Fortunately there is no lack of men in the Indian Medical Service well able to undertake and to complete the task and I have great hopes that some officer of that service will devote himself to the printed records of medical work in India with a view to demonstrating the hidden wealth that is contained therein.

I am writing to the editor of the *Indian Medical Gazette* to suggest the publication of a special "Intestinal Parasites" number, which would, I feel certain, furnish most interesting reading and afford a means by which many of the accounts of the ascaris lumbricoides and the symptoms to which its presence give rise contained in British text-books could be both amplified and made more correct.

I am, Sirs, yours faithfully,
A. E. GRANT,
Ennore, Boscombe, Oct. 11th, 1903. Major, Indian Medical Service.

MEDICAL ACTS AMENDMENT BILL.

To the Editors of THE LANCET.

SIRS,—I am requested by the council of the Association of Physicians and Surgeons of the Society of Apothecaries, Limited, to draw your attention to the following resolutions on the above-mentioned subject:—

[illegible]

1. That all persons registered under the Medical Act of [illegible] in respect to qualifications to practise medicine shall henceforth be described as physicians and all persons registered in respect of qualifications to practise surgery shall henceforth be described as surgeons.

2. That all persons registered under the amending Act and under the Medical Act of 1886 shall be described as physicians and surgeons.

---

[1] THE LANCET, Oct. 10th, 1903, p. 1030.

[1] THE LANCET, Sept. 26th, 1903, p. 893.

Dr. Vajda, Dr. Grünfeld, Dr. Nobl, and Dr. Weidenfeld); on the use of the Rœntgen rays (Dr. Schiff and Dr. Holzknecht); on mental and nervous diseases (Dr. Fritsch, Dr. Hollaender, Dr. Hirschl, Dr. Redlich, Dr. Elzholz, Dr. Sölder, Dr. Bischof, and Dr. Halban); on physiological and pathological chemistry (Dr. Mauthner and Dr. Fraenkel); on hygiene and bacteriology (Dr. Schattenfroh and Dr. Grassberger); and on forensic medicine (Dr. Kolisko and Dr. Richter).

In Vienna the cost of living is higher than in German cities. In the immediate vicinity of the General Hospital there are a great number of English "pensions" where the charges are from three to six florins a day, but many students prefer to live in single furnished rooms, the cost of which is from 15 to 40 florins a month, and to have their meals *à la carte* in a restaurant, except breakfast which is taken at one of the numerous coffee-houses, where also English and American journals may be read. Residence in Vienna is especially enjoyable in the summer season, when spare time may be spent in making excursions to the pleasant mountain resorts in the vicinity.

Vienna is the only city in which students can attend a complete medical curriculum without having to lose time in proceeding from one lecture to another. The courses for post-graduates are delivered during the whole year. The language of the lecturers is German but many teachers give special English courses and in many courses a short explanation is given in English if English students are attending them. The courses are mostly practical and the theoretical explanations given are as short as possible. Austrian patients submit to clinical examination with more willingness than is the case in other places. In some courses the students are permitted to perform small operations on patients. On account of the large number of subjects in the pathological institute Vienna is an excellent place for courses of operations on the dead body. The duration of most of the courses varies from four to six weeks, the fees for a single course varying between 15 and 50 florins (£1 10*s.* to £4). The number of attending students is generally limited to 10 or 15, in some courses (practical midwifery) even to four students. It is possible to make arrangements for private courses for a few persons at a special payment. Some courses are so overcrowded that it is necessary to make arrangements weeks or months before the beginning in order to get entrance. Gratuitous information with respect to courses of instruction, lodgings, and such subjects may be obtained from Dr. B Beer, IX. Maximilianplatz 13. Details as to lectures and laboratory courses are supplied by the Decanat of the medical faculty of the University.

Obituary.

WILLIAM JOHNSON WALSHAM, M.B., C.M. ABERD., F.R.C.S. ENG.,

SURGEON TO ST. BARTHOLOMEW'S HOSPITAL.

St. Bartholomew's Hospital and its Medical School have suffered great losses during the present year. Dr. P. H. Hensley, Mr. H. T. Butlin, and Professor Howard Marsh have resigned since last spring, and Mr. W. J. Walsham's untimely death has now caused profound sorrow to the many generations of students whom he taught so assiduously and with such pleasure first anatomy and afterwards surgery.

Mr. Walsham was born in London on June 27th, 1847, the elder son of Mr. William Walker Walsham of Wisbech, Cambridgeshire, and of Louisa Johnson his wife. He was educated privately at Highbury under the Rev. Dr. Johnson and early in life showed so great a mechanical bent that he was apprenticed to the engineering firm of Messrs. Maudslay. But the early hours and the physical labour required in the "shops" soon proved too much for his strength and he was compelled reluctantly to turn his attention to less exacting work. He studied chemistry for a time and it was through this source that his thoughts were first turned towards medicine. Late in September, 1867, he was walking down Chancery-lane to enter himself as a student at King's College, but on the way he met a friend who gave him so glowing an account of St. Bartholomew's Hospital that he straightway turned round and entered his name there. He was at this time a year or two older than the majority of his fellow students and he at once demonstrated his intellectual superiority and his manual dexterity by obtaining the chief prizes in the dissecting room, the treasurer's or junior practical anatomy prize being awarded to him at the end of his first winter session in 1868 and the Foster or senior practical anatomy prize falling to his lot at the end of his second winter session in 1869 In 1869, too, he obtained the senior scholarship in anatomy, physiology, and botany, having previously gained the junior scholarship. In each of these four events Mr. Alban Doran was placed second. Walsham also obtained a prize dressership under Sir James Paget and in 1869 was awarded the gold medal given by the Society of Apothecaries for proficiency in materia medica and pharmaceutical chemistry and was admitted an L.S.A. He afterwards went to Aberdeen, as was then the custom of many St. Bartholomew's Hospital men, and graduated there in 1871 as M.B, C.M., with the highest honours and with special honours for his thesis, and he returned to London to take the M R C.S. Eng. on Nov. 17th, 1871. He was nominated by Dr. Francis Harris to act as house physician at St Bartholomew's Hospital from May 1st, 1871, and this post he filled for nine months when he exchanged with Mr. Charles Irving and became house surgeon to Mr. Holmes Coote for three months. He then thought of going into private practice, but, an opportunity occurring, he was appointed assistant demonstrator of anatomy in 1872. In the next year he became full demonstrator, a position which he held until 1880, and the museum still contains some of his exquisite dissections. In 1880 he became demonstrator of practical surgery, in 1889 he was appointed lecturer on anatomy, and in 1897 he exchanged this lectureship for the post of lecturer on surgery. Mr. Walsham was elected to the office of assistant surgeon on March 10th, 1881. He was immediately afterwards appointed demonstrator of orthopædic surgery in succession to Mr. Howard Marsh and this position he held with immense advantage to the pupils in this department until his appointment as full surgeon to the hospital in 1897. He was elected surgeon to the Metropolitan Hospital and to the Royal Hospital for Diseases of the Chest in 1876 and he held the latter position for about eight years. At the Metropolitan Hospital he took charge of the department for diseases of the throat and he was elected to the position of consulting surgeon in 1896. Later, in the capacity of consulting surgeon, he became attached to the Sevenoaks Hospital for Diseases of the Hip and to the Bromley Cottage Hospital.

At the Royal College of Surgeons of England Mr. Walsham was elected a Fellow after examination on June 10th, 1875. He served the office of examiner in anatomy on the Conjoint Board from 1892 to 1897 and was a member of the Court of Examiners from 1897 to 1902 but found the duties of the latter office so trying that he did not seek re-election at the expiration of his first term of office. He filled several sectional offices in the British Medical Association and he was a member of the chief London medical societies.

During the present year Mr. Walsham had not appeared to be quite in his ordinary good health and it is certain that he had felt some failure of his usual energy, for he had made arrangements with his assistant surgeon, Mr. D'Arcy Power, to be permanently relieved of his night work at St. Bartholomew's Hospital, but it was not until within a few weeks of leaving for his holiday that some of his most intimate friends recognised that he was really ill. He was then advised to take a prolonged rest and left for Switzerland. He stayed for three weeks at Grindelwald but did not derive so much benefit from the mountain air as he had anticipated, and on August 27th he went to Wiesbaden. There, on the following day, serious symptoms of breathlessness developed. He was attended most assiduously by his brother, Dr. Hugh Walsham, and by Dr. H. Pfeiffer, whilst on two occasions Sir Lauder Brunton travelled from Switzerland to see him. The symptoms showed no signs of abatement and at his own earnest desire he was brought to England on Sept. 25th. His friends, Sir Lauder Brunton, Dr J. F. Goodhart, and Dr. F. de Havilland Hall, were unceasing in their attentions, but in spite of all that could be done he sank gradually and died peacefully in his sleep in the early morning of Oct. 5th. He married in 1876 Edith, the elder daughter of Joseph Huntley Spencer of Hastings, and had no family.

Perhaps the most marked features of Mr. Walsham's life were his fixity of purpose and his untiring industry. In physical appearance he must very closely have resembled his great predecessor at St. Bartholomew's Hospital, Dr.

WILLIAM JOHNSON WALSHAM, F R C S

William Harvey, the discoverer of the circulation of the blood. Indeed, the description of the one applies equally to the other. "A man of the lowest stature ...... rapid in his utterance, choleric." Yet he was beautifully made and in perfect proportion; his hand so small that he could easily pass it through an incision where another could not introduce more than three fingers, and he once wrote a paper to demonstrate the advantage of diagnosis by passing the whole hand into the rectum. His literary efforts were numerous and when he became busy with practice he still found time to give many addresses, some of which were published separately, whilst his works on diseases of the nose and deformities of the foot are well known. "The Theory and Practice of Surgery," which has reached an eighth edition, kept him fully employed, and there is too much reason to fear that the work of preparing the last edition proved the breaking strain for his powers already overworked. As a surgeon he was a neat and, when occasion arose, a daring operator, always ready to try new methods but usually falling back upon those to which he had accustomed himself. An accomplished mechanician he rarely troubled to use complicated appliances and was content to carry out his end with the simplest tools. His knowledge of anatomy often stood him in good stead and to the last the dissection of a difficult tumour or the avoidance of unnecessary bleeding by a knowledge of the position of the vessels was a source of unfailing pleasure to him. But if he was an excellent surgeon he was even more excellent as a teacher. A long training in the dissecting rooms and a prolonged tenure of office in the out-patient room made him a teacher of the highest order and enabled him to make all things clear to his hearers with a minimum of exertion on his own part. His hospitality and his social abilities were also of a very high order and gained him the respect and friendship of a large circle. He was especially prominent as a Freemason and attained to the position of Past Grand Deacon; he was very actively concerned in the founding of the Rahere Lodge, the first of the lodges established in connexion with the great metropolitan hospitals, and also in the founding of the William Harvey Chapter, of which he was, at the time of his death, one of the principal officers.

Mr. Walsham was buried at Highgate Cemetery on Oct. 9th, the funeral being attended by a large number of his colleagues and friends. There was also a memorial service in the church at St. Bartholomew the Less which was literally full to overflowing and was conducted in the presence of the whole staff of the Bromley Cottage Hospital who came up to London to testify to the respect in which they held their friend and consulting surgeon.

THOMAS JAMES PICKBURN, M.D., C.M. ABERD., M.R.C.S. ENG., L.S.A.

DR. THOMAS JAMES PICKBURN died suddenly at his consulting rooms, College-street, Sydney, just after seeing a patient. He had been in failing health for some time Dr. Pickburn was born in London in 1846 and was the son of Mr. J. T. Pickburn, founder and original proprietor of the London *Daily Chronicle*. His education was begun at the Aylesbury Grammar School and completed at the University of Aberdeen. His medical studies were pursued at St. Bartholomew's Hospital, London. After a successful course the deceased obtained the diploma of L.S.A. Lond. in 1868 and the degree of M.B. and C.M. Aberd. in the same year. Dr. Pickburn arrived in New South Wales some 35 years ago and began the practice of his profession at Braidwood. He was subsequently at Terara and was also assistant to the late Dr. Steer Bowker, M.L.C., at Newcastle. After spending a year in practice at Walcha he left for England where he took his M.D. degree. Upon his return to Sydney Dr. Pickburn established himself in College street, where he practised for the past 25 years. For the last six years he was in partnership with Dr. A. Maitland Gledden. The deceased gentleman was for some years honorary physician at St. Vincent's and Sydney Hospitals He was twice married and leaves a widow and a numerous family.

LONGEVITY.—The local newspapers report that a Mrs. Ann Howells, of Tonna, near Neath, is 106 years of

THE
ELEVENTH INTERNATIONAL CONGRESS OF HYGIENE AND DEMOGRAPHY.

(FROM OUR SPECIAL SANITARY COMMISSIONER.)

THE FOURTH SECTION.

Lead Poisoning.

AFTER the lengthy discussion on ankylostomiasis the Fourth Section took in hand the question of lead poisoning. Seven reporters had been appointed and their reports were printed separately. In fact, this was the method, or rather the lack of method, that prevailed throughout. On hearing that various reporters had been appointed to deal with each question it was natural to suppose that, for instance, the seven reporters on lead poisoning would issue a joint report giving the points and the recommendations on which they were all agreed. Instead of this each reporter issued a report of his own. It represented only his individual opinion and naturally there was a great deal of repetition, for the various reporters frequently travelled over the same ground. Then the section, instead of having to vote on some motions that represented the joint opinions of the reporters, found that it had to select from seven different sets of motions or recommendations. At the same time, it must be confessed that this was probably inevitable, as the reporters lived too far apart to be able to meet and to agree. In this case, for instance, two of the reporters live at Liège, while the other five reside at Bordeaux, Turin, Arnsberg in Germany, Newcastle-on-Tyne, and Selmeczbanya in Hungary.

Dr. THOMAS OLIVER in his able report presented a good description of the position of the problem in England and the recent attempts to improve the condition of the lead glaze in the hardware and porcelain making. Addressing the section, Dr. Oliver pointed out the similitude of the symptoms of lead colic and those of appendicitis. Then he explained that while employed in works where lead was used the workmen seemed to acquire an immunity which they lost if they ceased to work for some time, and therefore fell ill on returning to work. He agreed with the proposals which other reporters had made that all persons engaged in the manipulation of lead should be examined medically. If once attacked by the effects of lead such persons when cured should not be allowed to return to the work as they acquired a predisposition to further illness of this nature. The anæmic also should be forbidden to work in trades where lead was employed. When appointed by the Home Secretary to investigate the matter in Staffordshire he had recommended that only leadless glaze should be made. In this he was strenuously opposed by the manufacturers, yet he could demonstrate that it was quite practical at least in many if not in all cases. The manufacturers maintained, however, that it could not always be done as cheaply as when lead was used. In France, where the question was more advanced than in England, there had been a strong agitation in favour of zinc. The evidence given in England by the house painters and decorators showed that they were still in favour of white lead, but in many cases the French law prohibited the use of lead and the French engineers found that oxide of zinc was as good. He thought that the use of special drinks should not be encouraged as it produced a false sense of security. Finally, Dr. Oliver alluded to the prevalence of miscarriages among the women employed in the manipulation of lead.

Dr. FIRKET, reporter from Liège, spoke as to the necessity of improving the methods of drawing away the vapours or smoke from the smelting works.

Dr THISQUEN, the other reporter from Liège, pointed out that in Belgium statistics seemed to show that miscarriages were much more frequent among women who worked where lead was used than among those employed in the linen weaving or flax trades. But in the former case only married women were questioned, while in the latter case the unmarried women were included, and these had good reason not to record all the cases of miscarriage that occurred. It was a matter on which trustworthy statistics could not easily be obtained.

Dr. GLIBERT spoke as to the danger of the zinc smelting works where sometimes half the workmen suffered from anæmia. Yet these were people who lived in rural districts, [illegible] their own [illegible] joy good health, Also they were fairly well paid. But though the distillation of zinc was done as in the laboratories, the apparatus was not so carefully made. Leakages occurred and there was much smoke. In all this smoke there was oxide of carbon. The workmen, therefore, suffered from want of oxygen, and there was also arsenic in the ore. Then the lead and the zinc works were often side by side, so that what mischief the one failed to accomplish was caused by the other. Also there was a doubt as to what were the earliest symptoms of lead and zinc poisoning. A slight blue mark on the gum was not sufficient evidence. Mercurial poisoning and other causes produced this. The lead-like complexion might be due simply to insufficient washing, or the hæmoglobin might be lessened in the blood in proportion to the length of exposure to the influence of lead. Colic was by no means diagnostic. Cases of appendicitis had also been mistaken for lead poisoning. Therefore the recognition of the condition in the earlier stages was not always easy.

Some conversation ensued as to the presence of lead, zinc, and arsenic, and as to the category of workmen who suffered most in the smelting works, and then Dr. T. M. LEGGE, representing the British Home Office, made a very interesting speech. He first described the protective measures that had been adopted in England. The law facilitated the collection of information and yet they required still more light. Since 1895 every medical practitioner must notify all cases of lead poisoning or of poisoning from any other mineral. He was paid three francs for each notification. The managers of factories were also obliged to notify to the Home Office, but it was the medical attendant who decided whether the symptoms were sufficiently clear to justify such notification. In districts where lead was rarely employed and such cases did not often happen the local practitioner might be somewhat puzzled. To insure uniformity on all these points a memorandum was issued and sent to 2000 certifying surgeons. The latter had to examine all children under 16 years who wished to work. Dr. Legge had received in the course of four years 3000 notifications of cases of saturnine poisoning. Though Dr. Oliver thought there was at the present time a diminution in the number of cases it did not seem to Dr. Legge as satisfactory unless it continued for many years. He thought the only road of entrance for the poison was by the mouth, otherwise none of those who worked with their bare arms in lead all day long could escape. Nor was it due to dirt. It was the dust that should be suppressed. Carriage painters were poisoned by scraping off the dry paint. Nevertheless, respirators were not practical and many of the regulations suggested were old and of proved inefficacy. Dr. Legge's remarks were especially useful and appropriate when he described the independent positions of the surgeons who had to notify to the Home Office all cases of poisoning.

After some further discussion the section adopted a lengthy enumeration of precautions that should be taken. While at work it was urged that facilities should be provided for the frequent rinsing of the mouth and for gargling. More especially before eating should the mouth be carefully washed, as also the face, the hands, and the nails. Before leaving the works the workpeople should change their clothes and should not go home without first removing from their persons all trace of their work. In respect to diet the workers must avoid vinegar and acidulated articles, taking in preference that which was salt. Beer and alcohol must only be drunk in very small quantities. The workers must promptly seek medical advice even when only slightly indisposed. The factories and workshops must be kept scrupulously clean. The greatest precautions must be taken when dangerous substances had to be used. For the workpeople so engaged a dining room and a dressing room must be provided and this in a place well away from any injurious dust. All that was necessary for baths, for washing, gargling, cleaning of nails, changing of clothes, &c., must be provided. Neither eating nor drinking must be allowed in the works. The workpeople must be forced to take a complete bath at least once a week. Before employing anyone on the works the employer must demand a medical certificate of fitness. The medical men who examine the workers should be approved and authorised by the State. A special register must be kept to give a record of these medical examinations, and they should be renewed from time to time. No person should be allowed to continue working who presents symptoms of saturnine intoxication. Anyone who has suffered twice and severely from this cause should not be allowed to work where lead is used nor should any person who refuses to take the necessary precautions or who is addicted to drink be so employed. The above is but an abbreviation of the small pamphlet which was adopted as a sort of resolution. The following paragraphs represent what in England would be considered as resolutions and were also adopted :—

> The Congress expresses the desire that a regular medical surveillance placed under administrative control should be rendered obligatory i[illegible]toxication may occur and that t[illegible]ation should be compulsory. [illegible] f saturnine intoxication is still s[illegible] Congress expresses the desire that new investigations should be made in this matter and that the question be placed on the agenda of the next congress.

On the proposal of the French delegate, Dr. LEMIÈRE, the discussion on this subject was terminated by the adoption of this third motion :—

> Seeing the poisonous character of all lead compounds the Congress desires that investigations should be made in view of suppressing, wherever possible, the use of lead and demands that every encouragement should be given to all researches which have for their purpose the discovery of inoffensive substances that could be utilised instead of salts of lead and all experiments having for their object the generalisation of their employment.

Over-pressure.

Professors of the universities of Brussels, Montpellier, Turin, and Berlin, Dr. DEMOOR, Dr. IMBERT, Dr. TREVES, and Dr. ZUNTZ, had each presented a report on the very important but complex question of excessive mental strain and overwork. It is so easy to speak of strain, pressure, and overwork, but it is much more difficult to define and to divide wholesome fatigue from injurious exhaustion. What are the physiological symptoms? How can they be detected in a manner that can serve as a practical basis for legislation? When and how can it be proved that there has been an abuse of human labour force?

Dr. R. H. SALTET, professor of hygiene at the Amsterdam University, opened the debate on this subject by seeking to establish a connexion between the calories of heat and the labour force of the individual. It was generally estimated that manual workers spent three-quarters of their wages for the essential needs of their existence. What out of this went to the production of animal heat? These biological facts might supply a basis to work upon.

Dr. TREVES of Turin dealt with some of the main arguments of his report. The first difficulty was to define fatigue, how did it affect the nerve centres that governed all the acts of the worker? They must not wait till the output decreased to say that the man was tired. There was the question of the difference of energy developed and that which was utilised. Some only used a fifth of their energy and some much more to accomplish identically the same task. This should be measured. The methods tried should be applied to different trades and thus they might establish scientifically what could and what could not be done without injury to health. All scientific men sought to reduce the hours of labour.

Dr. IMBERT of Montpellier briefly related the main contentions of his report. He also insisted on physiological methods of defining fatigue and thought that such means were available, though those employed outside the laboratory could not be very precise. Dealing with ordinary fatigue, not with over-pressure, it was noticeable that the majority of accidents occurred when the workers were tired. The workman's brain saw or was conscious of the danger and would act accordingly. Experimentally it could be demonstrated how much time was required for this sort of nerve telegraphy to work. If the man was tired it worked more slowly and sometimes not quickly enough to enable him to get out of the way or to do whatever was necessary to avoid the accident that threatened him. There was much to be learnt by collecting statistics relating to labour accidents, not merely per day but above all per hour. He had collected such statistics in regard to 2000 stone workers and 1500 transport workers and the diagrams showed that there were twice as many accidents towards the end as there were at the beginning of the day. He then spoke at length as to the alteration of the muscular movements and of the method of doing a particular piece of muscular work as fatigue gained upon the worker. In a march, for instance, they had first the light, bounding, elastic step and then the dragging step of the fatigued walker. This modification might be chronicled by the use of kinematographic photography. For this no scientific instrument or even scientific knowledge was required. In the kinematograph they might find the means of recording and of proving the existence of over-pressure.

Professor **ZUNTZ** of the Berlin University thought that when *fatigue was produced by excessive muscular effort* there resulted a disturbance in the circulatory and respiratory systems. This was followed by trouble in the digestive and urinary organs and the most exact measure of the extent of the fatigue could be obtained by the comparative analyses of gaseous exchanges that took place before and after the work. They had to study the difference in the amount of the gases, the carbonic acid, the vapour and the secretions generally of the worker. The combustion of such gases increased in performing the same work when the worker was tired. The careful observation of the pulse, the increasing elongation of the systole, and the reduction of the diastolic pause were excellent criterions of fatigue. When they had a loss of weight caused by the fact that the activity of the digestive [illegible] in the same proportion as the [illegible] r proof that the work was excessive. When the enforced excess of work was very marked then it was the kidneys that should be more especially observed. The appearance of albumin and of cylindroids in the urine showed that there had been over-pressure, and if this be the only cause of these symptoms then they would generally and rapidly disappear when the patient was enabled to enjoy sufficient rest.

Mademoiselle J. **JOTEYKO**, M.D., demonstrator of physics at the Brussels University, spoke next and her observations were listened to with marked attention, for it was known that this lady had devoted much thought to the study of the subject before the section. Mademoiselle Joteyko first insisted that it was "the duty of all concerned not to allow persons to engage in work for which they were manifestly unfit." It was surprising how this obvious advice *was very widely disregarded. Children should be examined* while quite young with a view of determining what they were fit for. In such examination it was very necessary to take into account the condition of their nervous systems. For such purposes there already existed laboratories in Brussels, Paris, and Berlin. For instance, there were many trades which involved a special strain on the eyesight. Before entering these trades were the eyes of the person concerned tested? There was in this no difficulty, the eyesight could easily be tested. Then, also, those who worked by the piece could be carefully and usefully observed. Certainly the spirit of emulation tended to defeat the accuracy of such observations. Excitement and emulation might cause quite an exceptional amount of work to be done and this without any apparent strain. But this did not last. It was efficacious only in so far as *it was exceptional. The workers soon settled down to a* constant output under constant mental and physical conditions and then they could estimate whether this output was more than was good for them. Also they must take into account the effect of machinery; the rhythm of a machine was more injurious than muscular movements.

At this stage the discussion was adjourned and on its resumption Dr. **DEMOOR** of Brussels pointed out the great difference between the experiments made with the aid of instruments and machinery in a laboratory and every-day toil in a workshop or factory. Fatigue manifested itself in a score of different ways To examine one or two details did not prove anything. If the economist showed there was a better output as a result of an eight hours day than of a ten hours day the physiologist would conclude that this was nature's law, but the physiologist judged from a totally different standpoint. *To establish a comparison he would* want to experiment on persons who had each of them the *same strength, the same food, the same home, the same air,* and, above all, the same psychological conditions. To get all this was quite impossible, but they had statistical evidence; there were the death-rate and sick-rate, only these were collective and did not deal with individual dispositions. From all this they must not conclude that nothing could be done; but the sociologist must not expect the physiologist to supply him with precise data that would apply to everyone and would enable the legislator to say so much work might be allowed and no more. The laboratory observations must be transported to the workshop The medical attendant could estimate the vitality of the individual and say whether he was equal to the average strength necessary in each trade.

Dr. **GLIBERT** of Brussels argued that they might take it as a basis that if the production of animal heat exceeded the power of recoupment then injury was done. Maret had shown that in walking the expenditure was great at first, then it was reduced, and again later it was augmented. This was quite different from the work of a machine. They did not need individual statistics, but averages, and if on an average evil results accrued in a particular trade it was a clear proof that the hours of labour should be reduced.

Dr. **DEJACE** wanted to know what constituted capacity to labour. Medical men were asked for certificates to that effect. Of course, a child aged 14 years was not fit to do a pitman's work but he might do some other work.

Dr. **IMBERT** said that heat was a residue not a factor in movement. It was to be found at the cessation of the contraction of the muscles. A primitive energy had made the muscle contract. Work was an expenditure of energy which produced the exterior and visible labour. When the effort concluded the heat then occurred as a residue of the effort. They could not as scientific men give figures and say how many hours should be taken off from the week's work in different trades. The matter must be studied not in the laboratories but in the trades themselves. The investigator must quit his laboratory and go into the factory. He proposed that this should be done and reports as to the results should be submitted to the next congress.

Dr. **TREVES** replied that to some extent this had been done. A man manipulating a weight of ten kilogrammes for a fixed time showed no sign of fatigue. It was only when his nerve strength was tested that it became evident that he was affected. When set to do the same work with a six-kilogramme weight the nerve action was not affected.

Mademoiselle **JOTEYKO** observed that some were predisposed to consumption; it was evident that they should not be allowed to work where there was a great deal of dust. Further, she protested that mathematical calculations should *not be set aside in spite of the errors. They had not mathe*matically estimated cerebral fatigue. However erroneous collective figures might be when applied to individuals the mean was useful as applied to a class.

M. **FONTAINE** (civil engineer) pointed out that especially in piecework the best group of workers set the pace. They produced the maximum without over fatigue but the inferior workers to keep up to this standard did over-work. The only limit in their case was collapse. What, however, was meant by the term *sermenage* (over-pressure)? One muscle or set of muscles might be over-worked; that was not over-pressure. All that was needed was not to stop work but to change the sort of work. Over-pressure was excessive nervous strain, not over-muscular effort.

Dr. **IMBERT** thought they might say that there was overwork when a night's rest did not suffice to re-establish the *normal conditions.*

Dr. **JULES FELIX** (Brussels) protested that they need not, under the pretext of being very scientific, seek to create unnecessary difficulties. They had experimental methods, they could judge with the aid of instruments and also by simply watching the workers. There was a state of fatigue which did not amount to actual illness but which should nevertheless be studied medically, for the real object was to act before illness set in. The speakers had sought to define various categories of fatigue but everything was interdependent. The fatigue of the muscle affected the brain and the brain-worker felt muscular fatigue. Bertholet and Claude Bernard had demonstrated that nothing could be done without the expansion of physical energy and to-day they had to take measures so that in the struggle for bare existence on the one side and the greedy gold-grabbing on the other *should not produce a serious deterioration of the race.*

Dr. **TREVES** said that over pressure was the spending of *more energy than was assimilated.*

Mademoiselle **JOTEYKO** argued that if they could define over-pressure that would show they knew all about it. The utility of the discussion was, on the contrary, due to the fact that they did not know. They might say that over-pressure existed when the effects were injurious. Mosso defined it as a condition when with greater effort less was produced. Also it might undoubtedly be proclaimed that there was over-pressure where the usual rest did not suffice to efface all the effects of the work.

At last the discussion terminated and after a good deal of conversation the following motions were carried:—

1. That in all countries where no such institutions exist a special medical service should be established to watch over the workers.

2. At the legal age for beginning to work the worker must produce a medical certificate of physical aptitude.

3. The Fourth Section considers that, in consequence of the insufficiency of the scientific knowledge at present possessed, it is not yet possible to supply an absolute basis for the organisation of labour in regard to fatigue.

4. The Fourth Section expresses the desire that there should be inscribed on the agenda of the next congress the study of fatigue in one or several selected trades; this study should be made with the aid of the different methods actually known and particularly by noting the attitudes assumed during work and by complete medical observations.

5. In view of the realisation of the preceding resolutions, it is extremely desirable that the Governments should facilitate in the largest measure possible the studies in regard to professional and trade-created fatigue.

LIVERPOOL.

(FROM OUR OWN CORRESPONDENT.)

University of Liverpool: Civic Celebration.

IN celebration of the inauguration of the University of Liverpool the Lord Mayor, on Oct. 5th, entertained at a banquet in the town-hall the Earl of Derby, the Chancellor, and a large number of representatives of other universities interested in education. The gathering numbered 160 and included (besides Lord Derby) Lord Kenyon, representing the University of Wales; the Lord Bishop of Liverpool, the Bishop of Bangor, Sir Alfred L. Jones, K.C.M.G., the Vice-Chancellor of the University of Cambridge, Sir William M. Banks, the Vice Chancellor of the University of London, and several mayors of neighbouring towns. The Lord Mayor, in an interesting speech tracing the origin of the University of Liverpool, proposed "The University of Liverpool," which was replied to by the Earl of Derby. His lordship said that the aspirations of their University were great—he would say illimitable. Having recited the number of chairs and lectureships connected with the University, he remarked that they represented the munificent sum of £186,300. The figures were large and if he were to say they were sufficient he would be in opposition to many around him. He hoped the governing body would endeavour to do its best to give all facilities to those desirous of obtaining degrees. The question had been asked whether the degrees of minor universities were to be regarded as having the honour of older universities. Many whose opinions were well worthy of belief thought that Germany had gained by the number of her institutions that had done much in spreading throughout the country instead of confining within comparatively narrow limits the means of learning. His colleagues and himself would endeavour to make this University what it should be. The toast of "The Makers" was submitted by Vice-Chancellor Dale who paid a warm tribute to the founders, and Sir Edward Lawrence and Sir John Brunner, two of the governors, responded. Other toasts included "The Victoria University of Manchester" and "The Universities in the United Kingdom," which were replied to by Dr. Hopkinson (Vice-Chancellor of Victoria University), the Vice Chancellor of the University of Cambridge, Lord Kenyon on behalf of the University of Wales, Professor Joly (University of Dublin), and the Rev. John Watson on behalf of the University of St. Andrews. The toast of "Education" was replied to by Professor Forsyth of Cambridge and Sir H. F. Hibbert, the chairman of the Lancashire education committee. The proceedings closed with the toast of "The Lord Mayor," which elicited the remark that a son of the Lord Mayor was the first student entered in the books of the new University.

The Medical Profession in Liverpool and St. Luke's Day.

The third annual service to members of the medical profession will be held on St. Luke's Day, Oct. 18th, which this year falls on a Sunday. The Ven. Archdeacon Madden has kindly granted the use of St. Luke's Church for the occasion. The sermon will be preached by the Right Rev. Dr. Jacob, the Bishop of St. Albans. All the necessary arrangements have been completed and there is every expectation that St. Luke's Church will be well filled by members of the medical profession (for whom the middle aisle will be reserved), by their wives and families, medical students, nurses, and the general public who will occupy the side aisles and west gallery. As on the occasion of the last two anniversaries, a collection will be made on behalf of the medical benevolent fund.

Health of Liverpool: Low Death-rate.

The death-rate of the city has not been so low for a number of years. The medical officer of health reported to the meeting of the health committee held on Oct. 8th that the death-rate was 17 6 per 1000 of the inhabitants, as against 21·9 per 1000 at the same period of last year. Small-pox has nearly been stamped out as there are only 21 patients in the corporation hospitals. Typhus fever is rather prevalent, there being at the present time 34 cases in hospital. There are 50 cases of typhoid fever, 38 cases of diphtheria, and 466 cases of scarlet fever in the hospitals. The committee expressed congratulations on the exceedingly low death-rate of the city and the approaching disappearance of small-pox cases.

Proposed New Corporate Public Baths.

The proposed new civic salt-water baths to be built at a cost of £75,000, the plans of which are awaiting the sanction of the city council, will be among the finest in the country. The accommodation will consist of one swimming bath 150 feet by 50 feet, a second one 75 feet by 40 feet, and one 60 feet by 30 feet for ladies; 125 private slipper, spray, and hydropathic baths; two suites of Turkish baths, one to accommodate 56 males and the other for 18 females; and also two suites of Russian baths for males and females. Between 500 and 600 bathers will be accommodated at the same time. The baths will be erected on the site of the present ones at the pierhead and the plans point to a very handsome edifice.

Birkenhead Borough Hospital: Opening of the Nurses' Home.

On Sept. 26th the nurses' home in connexion with the Birkenhead Borough Hospital was formally opened by Sir Elliott Lees, Bart, D.S O., M.P, in the presence of a large gathering of ladies and gentlemen interested in the institution. The proceedings, which took place in a large marquee erected at the side of the home, were presided over by Mr. Egerton K. Laird. The chairman briefly called on Alderman W. T. Fiddes, one of the oldest members of the committee, who gave a sketch of the institution since its foundation 75 years ago. He said that the present building was given to the town by Mr. John Laird in 1862, at which date he was the Member of Parliament for Birkenhead. Three wards were built and 25 years ago the late Mr. William Laird enlarged the building. Like all others the hospital had had a chequered career, generally being impecunious. A great deal had been done for it by benevolent townsmen, while Alderman Shaw, during his year of mayoralty (1895) stirred up the public to such an extent that £700 were produced to wipe off the debt and £100 were added to the list of subscriptions. In 1897 Mr. John Pennock, the then mayor, raised a fund of about £4500; £3200 were devoted to the cost of the public ward, Mrs. John Laird giving a large sum for furnishing the whole of the new building. From that time to 1900 the public were allowed a little peace but in the latter year further appeals were made for a new home which were met with exceeding generosity. For the furnishing and decorating of the magnificent dining and day rooms the committee was indebted to Mrs. William Laird and to the corporation, which had dealt liberally with the committee in the disposal of the site for the new home, grateful thanks were also due. Sir Elliott Lees was then called upon to declare the home open and, in doing so, he said that it had been suggested to him that, as he would that day meet many of his most influential constituents, it would be a good opportunity to declare his views upon the fiscal question. He could say, sincerely, that they were prepared to support preferential treatment of the sick and he earnestly hoped that the nurses might get adequate protection in their new home. To that he could add that they would welcome free imports from every quarter of the globe in the shape of subscriptions and donations He expressed confidence that the new home would materially strengthen the potentialities for good of the hospital. He then formally declared the building open. The new building, which is at the rear of the hospital proper, is L-shaped in plan, the entrance being from Livingstone street. It is very compact in design and of handsome appearance, being faced with grey brick and red Ruabon moulded brick. There are two floors, the ground-floor rooms including a large dining hall and nurses' day room which have been furnished by Mrs. William Laird in memory of her late husband to whom they are dedicated and his portrait and a brass tablet are placed in the dining hall. The two rooms can be thrown into one as a large assembly room. There are over 20 bedrooms for the nurses and domestic staff, a sitting room for nurses, store room, pantry, &c. Special provision is made for egress in case of fire, the ventilation is well provided for, and the building is fitted throughout with electric lights the cost of which has been defrayed by Mr. E. K. Laird.

Professor Sherrington and the University of Toronto.

At the invitation of the University of Toronto Professor C. S. Sherrington, F.R.S., of the University of Liverpool, opened, and delivered the inaugural address at, the newly built medical school of the University of Toronto which now possesses one of the finest medical schools in the world. On this occasion the University of Toronto conferred upon Professor Sherrington the honorary degree of LL.D.

Oct. 13th.

WALES AND WESTERN COUNTIES NOTES.

(FROM OUR OWN CORRESPONDENTS.)

Typhoid Fever at Bridgend.

THE prevalence of typhoid fever in Bridgend, which is one of the oldest towns in Glamorganshire and has a population of about 7000 persons, has been commented upon yearly in his reports to the urban district council by the medical officer of health (Mr. Wyndham Randall). In the year 1898 there were as many as 49 cases and five deaths and in 1901 there were 32 cases and two deaths. The disease has occurred in almost every month of the year and not only during the autumn and early winter. Mr. Randall has repeatedly told the sanitary authority that he considered the cause of the disease to be in the soil which had long been liable to pollution. Badly paved yards, too, in his opinion, added their quota to the liability to local infection. Until recently there was no general system of sewerage in the town and what sewers existed were defective, the houses being provided with pail closets and cesspits, but there has now been completed a new outfall sewer discharging into the sea about five miles from the town. During 1901 the water-supply of the district was placed under suspicion and the bacteriological examinations made at the Cardiff and county public health laboratory were not at all satisfactory. In the early part of this year, therefore, Dr. H. Timbrell Bulstrode made an inspection of the locality on behalf of the Local Government Board and in the report which has just been issued by the Board Dr. Bulstrode indorses to a great extent the opinion of the medical officer of health, though he considers that certain facts which he has ascertained in the course of his investigations may point to contamination of the water. He advises that the present source of supply should either be abandoned or subjected to adequate filtration. The latter course is being adopted by the water company.

Gloucestershire Health Report.

During the six years 1894–99 a statistical summary of the annual reports of the district medical officers of health in Gloucestershire was prepared by the chairman of the sanitary committee of the county council. A more extended summary was made in the two subsequent years by Mr. G. H. Fosbroke, the county medical officer of Worcestershire, and for the year 1902 a report has been made by Dr. J. Middleton Martin who has been appointed medical officer to the county while retaining his appointments as medical officer of health of the urban and rural districts of Stroud. The administrative county had a population at the middle of 1902 of 332 460, and there was a birth-rate during the year of 28 6 per 1000. The death-rate was 14 2 per 1000 but corrected for age and sex distribution this latter rate was only 12 8 per 1000. The position of the county as regards provision for the isolation of cases of infectious disease is far from satisfactory. In 12 of the 37 sanitary districts with an aggregate population of nearly 73,000 persons there is no isolation accommodation at all and in many of the remaining districts the accommodation is quite inadequate. Dr. Martin suggests that the county council should contribute towards the cost of erecting suitable hospitals in the county. In the section dealing with schools Dr. Martin urges the great importance of giving lessons in hygiene and advises that all teachers appointed in the future should be required to show a reasonable knowledge of hygiene and that lessons in elementary hygiene should be given in all schools, more particularly to the older girls.

Memorial to the late Mr. Charles Highett.

On Oct. 3rd the Lord Mayor of Bristol formally opened a boys' club in St. Werburgh's, Bristol, which has been erected as a memorial to the late Mr. Charles Highett, M.R C.P. Edin., who was mayor of Bristol in 1892. The Lord Mayor also unveiled an excellent portrait of the deceased, underneath which was the inscription on a stone tablet: "To the glory of God and in memory of Dr. Charles Highett who died April 20th, 1896."

Poor-law Conference at Exeter.

At the Poor-law Conference which has just been held at Exeter a considerable time was occupied in discussing the treatment of the feeble-minded. The general opinion seemed to be that the Commissioners in Lunacy should facilitate the establishment of separate institutions for the treatment of imbeciles, the view being expressed that these institutions would be less expensive than lunatic asylums, that the comfort of the inmates would be greater, and that their training would be more easily carried out.

IRELAND

(FROM OUR OWN CORRESPONDENTS.)

Meath Hospital and County of Dublin Infirmary.

THE opening meeting for the winter session took place at the Meath Hospital on Oct. 12th, when an address was delivered by Sir Philip Smyly, one of the surgeons to the institution. On the motion of Sir J. W. Moore, seconded by Sir Lambert H. Ormsby, President of the Royal College of Surgeons, the chair was taken by Sir Francis R. Cruise. Sir Philip Smyly in his address alluded to the serious loss the hospital had sustained by the death of Sir William Stokes who sacrificed his life for his country but not before he had made a high name for himself as a surgeon and perpetuated the reputation of his father, William Stokes, who long ago, with Graves, had made the Meath Hospital famous. The hospital is, of course, one of the oldest in Ireland and this year completes its third jubilee.

Death of Mr. John Roche, M.D., M.Ch. R.U.I.

A cablegram announcing the death of Dr. John Roche has recently been received from Heidelberg, South Africa, where he was staying on a visit to his son. Dr. Roche was for many years a well-known resident in Kingstown. He was highly popular in the district and much respected. He was a distinguished graduate and prizeman of the Royal University of Ireland and in 1885 obtained the degree of D.Sc. R.U.I. Dr. Roche served in the Indian Medical Service for many years and was the author of numerous contributions to medical literature. He was a justice of the peace for the county of Dublin.

Infectious Diseases in Belfast.

The second attempt of the public health committee of the city of Belfast to get the guardians to convert the Belfast workhouse fever hospital into a district hospital and to utilise it for the period during which their own city fever hospital (three years) will be in process of building has ended, as might have been anticipated, in another failure, the following motion having been carried by 23 votes to three:—

> That this board fully recognises the urgent need of additional accommodation for the treatment of infectious diseases, but begs to

The leader of the minority stated that if the debate had the object of making the corporation do what it should he for one would be perfectly satisfied. The public health committee is now *in statu quo* and must either take the old Royal Hospital or build temporary infectious wards at Purdysburn where the new infectious diseases hospital is to be built.

Forster Green Hospital, Belfast.

At a meeting of the supporters of this hospital held on Oct. 10th it was reported that during the past nine months 150 cases had been treated, 71 men and 79 women. It has been decided to fit up an apparatus whereby the Roentgen rays can be used for diagnosis and treatment. Through the help of Mr. Forster Green and other friends a debit balance of £336 2*s.* 11*d.* has been wiped out. The beds have been all occupied and those in the open air are most liked by the patients.

Belfast Lunatic Asylum.

The authorities of the Belfast Asylum have been using the emergency buildings erected at Purdysburn by the city corporation for small-pox patients, but a letter was received by the asylums board on Oct. 12th to the effect that the inspector of lunacy objected to this because wood-lined buildings were dangerous, especially in the winter months, owing to the risk of fire from heating and lighting. The board is to convey and to remove the 50 patients from these buildings. Evidently the experience of Colney Hatch has frightened the asylum control authorities.

Armagh Asylum.

At the monthly meeting of this asylum board held on Oct. 12th the report of the inspector of asylums was read, showing that the average capital cost of maintenance during the year ended March 31st, 1903, was £21 4*s.* 6*d.*—a proof that no complaint could be made on the score of expenditure. The inspector suggests a plan to get rid of the overcrowding. It has been decided to provide looms for the patients to work, a plan that has been introduced with success into the Richmond Asylum as well as into five other county asylums in Ireland.

Irish University Education.

The air is again full of rumours in reference to coming legislation in the next session of Parliament with regard to Irish university education. Some think it will take the form of a Roman Catholic university, while others assert that a scheme is "cut and dried" for the turning of the University of Dublin into a national university with three affiliated colleges, Trinity College, Dublin, a new fully endowed Roman Catholic college in Dublin, and Queen's College, Belfast. Whatever shape the measure may ultimately take everyone believes that preliminary steps are being taken in the matter.

The Royal Victoria Hospital, Belfast.

The winter session 1903-04 is to be inaugurated so far as clinical teaching is concerned in Belfast by an opening address at the Royal Victoria Hospital on Oct 22nd, to be given by the chairman of the medical and surgical staff, Dr. J. Walton Browne. Since the end of the summer session the removal to the new hospital has taken place; the arrangements there are excellent for treating the patients and for clinical teaching.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

A New Treatment for Infantile Gastro-enteritis.

M. Henri de Rothschild, who founded a very well-appointed dispensary for infants, has there made a study of gastro-enteritis, a disease which is so fatal in infants that during some weeks of the year it brings about a mortality of 200 per week. On Oct. 13th M. de Rothschild stated at the Academy of Medicine that despite all the treatments which he had employed he had never been able to bring the mortality below 50 per cent. When, however, acting on the advice of M. Roux and M. Metchnikoff, he had treated his patients with skimmed milk to which 10 per cent. of lactic acid had been added the malady was nipped in the bud and between June 1st and Oct. 1st he had treated 14 cases at his dispensary, all of which had recovered.

The International Sanitary Conference at Paris.

Following on the recent International Conference in Venice, another conference, to round off the regulations to be taken against plague and cholera in Europe and the East, has just met at Paris, commencing on Oct. 10th. The conference was due to an invitation addressed to the Powers by Italy. M. Barrère, the French Ambassador to Italy, who presided over the Paris Conference in 1894 and who was the representative of France at the conference held at Venice and at Dresden, presided over the French delegates at this conference. No information of the proceedings of the conference has been communicated to the press up to the time at which I write, so I presume that nothing of importance has been accomplished.

The Inspection of Butcher's Meat.

Paris is greatly excited at the present moment over the sale of butcher's meat. Animals intended for food are killed in the municipal abattoirs where the carcasses are examined by special sanitary examiners who inspect all the viscera and have the right to prevent any meat being taken out of the abattoirs for delivery to the meat salesmen for sale to the public if the animal from which such meat comes shows on examination of its viscera that it has been affected with tuberculosis, glanders, or measles (*ladrerie*). On this side of the matter therefore the health of Paris is carefully looked after for no animal may be killed in any shop for the sale of meat within the town of Paris itself and all private slaughter-houses have for some time past been abolished. Unfortunately, however, there exists in the central markets a traffic in meat which comes from various quarters—that is to say, from the suburbs, from the provinces, and even from abroad. Such meat is brought into Paris already cut up and the sanitary inspectors exercise supervision over it in the central market and can seize and order to be destroyed any pieces which they suspect, but this inspection can only deal with the question as to whether the meat is fresh or not, for once the viscera have been removed it is not possible for a superficial examination to eliminate the existence of such diseases as tuberculosis. The animals from which such meat comes have been killed in the country, in private abattoirs, where the carcasses are subjected to no examination, for sanitary inspection is only organised in the big towns and it would be impossible to organise a corps of sanitary inspectors for each village where any butcher is at liberty to kill his own beasts. This fact is well known to cattle merchants and butchers who very often buy up sick beasts which would certainly be refused at the public abattoir, send them into the country, kill them there, and bring them back in separate pieces as meat for sale. As they buy up these sick beasts at a very low price they make handsome profits at the expense of the public health. The daily journals have begun to discuss this question and the authorities of the municipal abattoirs are much concerned to find that so many little private slaughter-houses, which have been suppressed in Paris, are undergoing resurrection in the country around.

Oct. 13th.

VIENNA.

(FROM OUR OWN CORRESPONDENT.)

Small-pox in Bosnia and Herzegovina.

AN interesting account of the occurrence of small-pox in Bosnia was recently given by Dr. Kobler of Serajevo in a paper read before a German society in that town. Before they were occupied by the Austrians in 1878 both Bosnia and Herzegovina were Turkish provinces and small-pox was everywhere endemic in them. Many elderly persons are still to be seen not only pitted with the disease but presenting cicatrices on the eyes and on the extremities. Statistical records of small-pox were commenced in the year 1880; in 1888 there were 14,177 cases and in 1889 there were 13,540 cases. Compulsory vaccination was introduced in 1883 and from that time till 1898 there were 772,691 vaccinations performed. The prevalence of the disease has fallen rapidly since the introduction of compulsory vaccination and in the year 1892 there was not one case in Bosnia and Herzegovina. Small centres of the disease still occur, the number of cases not exceeding 20 or 30 per annum. These places are only on the Turkish and Montenegrin frontier and the patients are immigrants from countries where vaccination is not compulsory. In Bosnia and Herzegovina there are some qualified females engaged in civilian medical practice who are of great use in the compulsory treatment of infectious diseases in the houses of Mahomedan women and in the harems, as male practitioners are never admitted in such circumstances, and the Mahomedan population have shown much opposition to the measures taken by the authorities for the prevention of small-pox and syphilis.

Syphilis in Bosnia and Herzegovina.

A paper on the distribution of syphilis was also read before the society by Dr. Glück of Serajevo. He said that the disease was brought into the country by the Osmans and that it became widely spread throughout the whole population. It was not uncommon for all the inhabitants of a village or small town to be infected. The Turkish surgeons treated it by fumigations with calomel, a method which is still in use as a domestic remedy in families Before the Austrian occupation in 1878 syphilis in Bosnia had the character of a malignant disease The ulcerative stage was early in its appearance, firstly in the skin and mucous membranes and then in the bones It was in most cases impossible to find the initial lesion and the frequency of extragenital syphilis was very remarkable The second stage of the disease presented itself as a syphilide under the form of lichen and similar symptoms attended a relapse of the second stage The frequent occurrence of this peculiar manifestation was due to malnutrition, anæmia, and predisposition to tuberculosis A question of very great interest was the extreme rarity of nervous sequelæ such as tabes dorsalis and general paralysis of the insane Notwithstanding the wide diffusion of syphilis in an endemic form only seven cases have been observed among the native population of Bosnia in the course of seven years The lunatic asylums are well filled, but in all of them only four cases have been found

The University of Vienna

During the last summer semester only 803 students (including 17 women) and 442 post graduate visitors attended the lectures and laboratories This diminution is due both to the depressed condition of the medical profession in Austria and also perhaps to the fact that the professors who used formerly to be [illegible] all passed away The [illegible] ceived the title of profes[illegible] Dr Edouard Spiegler (dermatology), Dr Max Sternberg (medicine), Dr Michael Grossmann (laryngology), and Dr Tandler (anatomy) Dr Karl Walko has been admitted as *privat docent* in the German University of Prague

The death of Dr Alexander Rollett, professor of physiology in the University of Graz is announced A pupil of Brücke he worked principally at the physiology and histology of the red blood corpuscle and the muscular and connective tissue He discovered the delomorphous and adelomorphous cells in the gastric glands at the same time as Professor Heidenhain of Breslau

Oct 12th

EGYPT.

(FROM OUR OWN CORRESPONDENT)

The Summer in Egypt

OLD Egyptians declare that the climate of Egypt has changed considerably in the last few years and their contention gains ground by the experience of the summer just drawing to a close The heat was never at any time excessive, though in July and August the humidity was much above the average The worst part of the summer is always in the early months, especially in June with its dry heat and dust, but as the year progresses a cool northerly breeze sets in every evening at sundown, almost with the regularity of a trade wind, thus insuring a cool night and a chance of refreshing sleep to enable one to stand the heat of the morrow With the improvement in the system and the increased area of land under irrigation the humidity has naturally increased, but at the present time, usually the dampest season of the year, the weather is splendid and so cool that it is no longer possible to dine in the open air unless well wrapped up For the benefit of your readers in England it may be recorded that there has hardly been a drop of rain in Cairo this year, and there has been nothing in the weather of this summer that might not have been quite well borne by the Englishman who has never crossed the Channel There has been the usual average of typhoid fever, which generally assumes the severe tropical form, but nothing like an epidemic although the mortality has been rather higher than usual The Nile flood has been a good average one this year and with skilful management of the barrages and careful regulation of the supply of water to the different canals there will be only a very small area of cultivable land unirrigated The cotton crop, however, is not good as the sun has not been hot enough or the air sufficiently dry to open the pods thoroughly To think that it is not hot enough in Egypt !

The Coming Season

The prospects for the coming season are exceptionally good There is no plague to speak of and there is no cholera (Unberufen !) and the weather promises to be delightful though rather colder than usual In an ordinary year visitors to Egypt should arrive in Cairo about the middle of November and should go straight up the river to Assouan Wady Halfa, or even Khartoum, if they wish it This is the best time for the river and on their return, from three to six weeks later, Cairo is at its best and remains until March a thing of beauty and a joy for those who love gaiety, excitement, and beautiful weather It must be remembered that December and January are quite cold enough for big fires and English winter clothing and that after the beginning of the New Year it is very cold on the river It is a great mistake to imagine that Egypt and Cairo particularly, is always hot Early in April at the latest the tourist should begin to wend his way homewards, *viâ* the south of Europe, if possible, although sometimes the weather in Cairo does not become very hot until May is well advanced This year from all appearances if the winter is to be at all in keeping with the summer, these dates should be put nearly a month earlier as regards the commencement of the season

Deaths in the Profession in Egypt

It is with sincere regret that I have to record the death of Dr George Atkins Rountree who has recently done such good work in Lower Egypt Dr Rountree qualified in Dublin in 1882 and first came to Egypt several years ago as medical officer to Cook's Nile steamers His next appointment was that of surgeon to the hospital of the firm at Luxor and less than two years ago he was appointed assistant inspector to the sanitary department of the Egyptian Government In this position his genial manners and tact and his capacity for hard work made him a most trustworthy officer and endeared him to all with whom he came in contact While on duty at Damietta he caught a severe cold and after lying very ill at Tantah for some days he was brought to Cairo with grave symptoms of lobar pneumonia He held his own for some time but finally died from heart failure on August 12th His death came as a great shock to his friends by whom he was universally liked and respected Mr A T White whose death took place less than a month later, was educated at Westminster Hospital and had done good work in Uganda before coming to Egypt to take charge of the hospital erected by Sir John Aird in connexion with the building of the Assouan barrage On the termination of this work Mr White was appointed an assistant inspector in the sanitary department and was stationed at Assiout After much hard work in this post, as a result of which his health, never very robust, suffered considerably, he went to Suez on holiday duty Here he contracted diphtheria in its most virulent septic form and in spite of antitoxin, tracheotomy, and the most careful treatment he died in less than a week from the tim[illegible]efinite symptoms He leaves a [illegible]ided for but it is hoped that w[illegible] gratuity and the efforts of friends she may be enabled to make both ends meet Mr White was a veritable slave to his work and his name must be added to the ever lengthening roll of those medical men who have met their death in the discharge of their duty He contracted the disease from a native patient whom he was treating

The Rarity of Appendicitis and other Surgical Abdominal Conditions in Egypt.

In these days, when the question of the increase in appendicitis is being so much discussed, it is interesting to observe that in a personal experience of over 2000 major operations among native Egyptians in the last five years only three cases of appendicitis have been met with It is a matter for conjecture whether this is due to the rigid [illegible]nned foods are eaten in [illegible] approaching a strenuous [illegible] the poorer classes and [illegible] to cold, in contrast [illegible]y the richer population, but to a surgeon in England it must be difficult to realise that in five years only three cases of appendicitis have occurred in a general hospital practice Abdominal conditions generally requiring surgical interference are also rare, for there are practically no gastric ulcer, no intussusception, and no malignant disease of the intestine By far the most usual form of intestinal obstruction is strangulated hernia, in fact, with the exception of three cases of volvulus of the descending colon and sigmoid flexure all other forms are quite curiosities Tuberculous peritonitis and tuberculous masses in the omentum or infection of the mesenteric glands are also very uncommon, but whether this is due to the small quantity of milk taken by the natives—for except for breast-feeding for the first year and sometimes two years a child rarely has milk of any kind—it is difficult to say. It is interesting to note, also, that bovine tuberculosis is not at all common in Egypt.

Cairo, Oct. 3rd.

AUSTRALIA.

(FROM OUR OWN CORRESPONDENT.)

Small-pox in Tasmania.

THE outbreak of small-pox at Launceston continues. The disease is in a virulent form, many of the cases being hæmorrhagic. Mr. J. S. C. Elkington of Melbourne has been engaged by the Government to advise generally regarding the outbreak. Every case is removed to the isolation hospital as soon as recognised. "Contacts" are placed in a special building, after a carbolic bath and a change of clothing. The old clothes are burnt and the houses are thoroughly disinfected. The outbreak has cost the Government about £10,000 already and is still causing an expenditure of about £270 a week.

Vaccination in New South Wales.

The President of the Board of Health has presented a memorandum to the Premier of New South Wales on vaccination. After pointing out the beneficial effect that vaccination had had in other countries the memorandum proceeds to show that New South Wales is the only State in the Commonwealth where there was no compulsory Vaccination Act. It might be inferred from that that the people were opposed to compulsory vaccination, but the only available evidence went to show that they held no strong opinion on the subject. They appeared not to oppose it but merely to neglect it. Whenever there was a small-pox scare the numbers who applied for vaccination for themselves or their children rose remarkably. During the epidemic in Sydney in 1879–80 the vaccinations voluntarily done amounted to nearly 60,000, although before and afterwards the number of people vaccinated in the years when there was no scare was so small in proportion to the total population as to be insignificant. There seemed to be no reason, therefore, for expecting that any great opposition would be offered to the passage of an Act rendering vaccination and revaccination compulsory, and as this State was not merely exposed to disaster itself from the want of such a law, but was consequently a perpetual menace to every other State, the Board of Health would once more urge that the introduction of a Vaccination Bill and the establishment of a calf lymph station should be taken into practical consideration without delay.

Leprosy in Victoria.

A Chinaman, carrying on business in one of the main streets of Melbourne, was found to be suffering from leprosy. He was promptly isolated and his shop and dwelling were placed under police surveillance. Arrangements have been made to convey him back to China in a cargo-boat.

Treatment of Consumptives.

Nothing has yet been done towards providing further hospital accommodation for cases of advanced consumption in indigent circumstances in Melbourne. Mr. Kronheimer has given a sum of £5000 towards the equipment of a building for the purpose but difference of opinion has arisen as to how and where it should be expended. The committee of the Austin Hospital for Incurables, where cases of tubercle are now received, proposed that the money should be spent in additions to the buildings there. To this the residents of Heidelberg, where the hospital is situated, object. The Minister of Health has recommended that Mr. Kronheimer's gift should be used to erect buildings at the Home for Indigent, Aged, and Infirm at the Royal Park. The inspector of charities reported to the Minister that the cost of maintaining consumptive patients at the Government institution—the Home—would be much less than at the Austin Hospital. The inspector has obviously based his estimates on a wrong conception. He has overlooked the fact that advanced cases of consumption require constant nursing and expensive nourishment and drugs.

The Age of Consent in New South Wales.

Dr. C. K. Mackellar has introduced into the Legislative Council of New South Wales a Girls' Protection Bill, the object of which is to give protection to girls under 17 years against all those offences under the Crimes Act which now applied to girls under 14 years of age. He pointed out that in England the age of protection was 16 years, in Tasmania 15 years, in New Zealand, Victoria, and West Australia 16 years, in South Australia 17 years, while in many American States it was 16 years and in others 17 years and 18 years. In New South Wales girls between 14 and 17 years were not sufficiently protected as regarded their personal purity by the law as it stood. The law presumed that a girl under 21 years was unable to make any legal or binding contract in regard to her property because she was presumed to be incapable of intelligently guarding her own interests in such transactions, but when she came to deal with her own personal purity, which should be as dear to her as life itself, she was afforded no protection whatever after attaining the age of 14 years. The unanimous opinion of the medical men whom he had consulted was that the sexual maturity of girls was practically the same in New South Wales as in European countries, and a very distinguished authority had said that there was little difference in this regard between India and England, the idea that warm latitudes had a great influence being erroneous. The statistics showed that in the ten years from 1893 to 1902 in New South Wales 4575 illegitimate children were born of girls 18 years of age and under, 2028 being 18 years old, and he thought that if any argument were wanting in favour of an alteration of the law they had it there. The Bill, with some minor amendments, was carried and reported for the third reading.

Declining Birth-rate.

The Government of New South Wales has appointed a Royal Commission to inquire into the decreasing birthrate of the State. It is issued to the following gentlemen: Dr. Mackellar, M L.C (president); Sir Henry Norman MacLaurin, M.D., LL.D., M.L.C.; Mr. Octavius C. Beale, president of the New South Wales Chamber of Manufactures; Mr. Timothy Augustine Coghlan, I.S.O, Government statistician; Mr. Joseph Foreman, M.R.C.P. Edin., &c.; Mr. Edmund Fosbery, C.M.G., Inspector General of Police; Mr William Arthur Holman, M L.A., barrister-at-law; the Right Hon. Thomas Hughes, Lord Mayor of Sydney; Mr. Edward William Knox, general manager, Colonial Sugar Refining Company, Limited; Mr. George Stanley Littlejohn, president of the Sydney Chamber of Commerce; Dr. John Brady Nash, M.L C.; and Dr. Robert Thomson Paton, Government Medical Officer.

Charges against Dr. Ramsay Smith, Coroner at Adelaide.

Dr. W. Ramsay Smith, who, it will be remembered, originally came to Adelaide to act as medical officer to the Adelaide Hospital when the honorary staff resigned and was subsequently appointed coroner and inspector of anatomy, has been suspended by the Government. He is charged with infringing the Anatomy Act which it is his duty to administer. A board, consisting of Commissioner Russell, Mr. Buchanan, Master of Supreme Court, and Dr. Torr, is inquiring into the charges. These are practically all of the same kind—viz., removing skulls, skeletons, and other anatomical structures from dead bodies and sending them to Edinburgh. As regards several of the cases the charge was that Dr. Smith improperly took advantage of his position as coroner to obtain skulls. Also that skeletons were taken from bodies contrary to law and not for purposes of anatomical study by medical students in the State. Voluminous correspondence was put in, including a long letter from Dr. Smith to the Chief Secretary, in which the following statement occurs:—"I further declare that the procuring, preparation, and export of these anthropological and other specimens was with the knowledge and concurrence of the Governments of the day. If I am to be charged and suspended, I think, as a matter of equal justice, the following gentlemen should be similarly treated:—Professor Watson, pathologist; Dr. Angas Johnson, assistant physician at the hospital; Professor Stirling, consulting surgeon; Dr. Rogers, honorary physician; Dr Verco, assistant gynæcologist; Dr. Smeaton, medical superintendent; Dr. Cleland of the asylum; and Dr. Stewart of Port Pirie. I do not suggest that these gentlemen have done anything wrong, but if they have not neither have I. I deny the illegality and assert that the charges are untrue. I have done nothing illegal, either at common law or under the Anatomy Act, or otherwise. In whatever has been done I have followed the practice recognised and adopted, not only in this State but throughout the civilised world I have not been guilty of any conduct rendering me unfit to remain in the civil service What I have done has always been for the advancement of science, for the alleviation of human suffering, and for the efficiency of my profession I cheerfully invite the fullest investigation of the whole subject "

The British Medical Association and the Australian Natives' Association in New South Wales

In May last a women s branch of the Australian Natives' Association was formed in Sydney and registered under the Friendly Societies Act Its main object was to be the attendance of its members by a medical woman The position of medical officer to the branch was advertised and a number of applications were received Dr Harriett Biffen was appointed The council of the New South Wales Branch of the British Medical Association then officially informed Dr Biffen, who is a member of the British Medical Association, that she could not accept the position as the Women's Native Association was one "inimical to the medical profession" As all the medical women in Sydney are members of the British Medical Association the Women s *Native Association is practically boycotted*

Hospital Affairs

Once more the scandalous quadrennial election of the whole of the honorary staff of the Melbourne Hospital has been held It had been hoped that this time the various positions would not be contested and that in this way the evils of the system of election by the subscribers would be avoided At the last moment, however, Dr H Maudsley, who holds the position of honorary physician at the Alfred Hospital, announced his intention of seeking election as physician to the Melbourne Hospital His friends, including ladies who are the leaders of society, made an energetic personal canvass of the subscribers with the result that Dr Maudsley was elected by a majority of about 60 votes out of some 2000 polled Dr J R MacInerney, who is thus displaced, has ably served the hospital for many years, first as physician to out patients and for 12 years as physician to in patients , he is an excellent clinical teacher and an expert bacteriologist, possessing a most completely equipped private laboratory It is to be hoped that the result of the election will cause a strenuous effort to be made once more to alter the system of election Proposals to this end have been recently made In February last representatives from the charitable hospitals of Victoria met in conference in Melbourne and appointed a committee to consider the Hospitals Act of 1890 with a view to suggest alterations and amendments in it. That committee has now finished its work and its report contains several important recommendations having for their object the better operation of hospital legislation In the first place it is suggested that the Hospital and Charities Act should be repealed and that a new statute should be enacted embracing all hospital, charitable, and philanthropic institutions in the State Recommendations are made for amendments which will more closely define the status of contributors, life members, and executors for voting purposes and include in the category representatives or nominees of persons or organisations, so that charitable hospitals may amend their by-laws and thus enable such representatives to take part in the allocation of contributions and in the management of hospitals to which the organisations subscribe Honorary office bearers should be elected by contributors personally present (not by proxy) who had paid their subscriptions In order to prevent imposition upon charitable hospitals by those able to pay for their treatment the committee thinks that the section dealing with this subject should indicate clearly

of the most important questions dealt with in the report has reference to the method of appointing honorary officers and the committee has formulated a scheme to apply only within a ten mile radius of Melbourne where the present system is felt to be objectionable alike to committees, subscribers, and the medical profession The scheme involves the appointment of an electoral college, consisting of four medical *practitioners, four representatives of metropolitan* hospital committees, and one member elected by Melbourne University The applications for honorary positions should be considered by such college together with two committee men from the particular hospital concerned The term of office for each member of the college should be ordinarily four years, subject to a graduated scale in the case of those first chosen Honorary medical officers elected by the college should hold office for seven years with the privilege of re election and should retire at the age of 60 years in the case of surgeons and 65 years in the case of physicians A resolution passed by an absolute majority of a hospital committee should be sufficient to remove a medical practitioner from the honorary staff —At the forty-sixth annual meeting of the Women's Hospital, Melbourne, the report presented stated that during the past year 442 patients received treatment in the infirmary department and 1489 in the midwifery department , 1105 infants were born in the hospital The out patient department showed a slight falling off, there being 1043 new patients, as against 1050 in the previous year The necessity for extra accommodation had been apparent for several years past, but the realisation of the hopes of the committee in that direction seemed to be as far off as ever Some patients had been awaiting admission for many months There was still the burden of an overdraft, notwithstanding that the annual expenditure had been reduced by about £580 The total income for maintenance was £7920, including the sum of £1000 transferred from the reserve fund very early in the year It scarcely reflected credit on the public that the institution should be in the unique position of not having any endowment fund The debt on the building fund had increased to £521 Funds were being collected for the enlargement of the cottage for the maintenance of cases of septicæmia the consent of the Board of Health having been obtained to extensions to cost £497 —At the annual meeting of the subscribers to St Vincent's Hospital, Melbourne, the Lord Mayor (Sir Samuel Gillott) presided and in opening the meeting called attention to the unfinished state of the new hospital, for which £15 000 had been subscribed *The foundations of the building had been* laid at a cost of £4000 which left £11,000 available for its completion Tenders had recently been called for this but the lowest tender for the work had been £28 000 It was therefore necessary to formulate some scheme for the augmentation of the fund in order that the erection of the buildings might be proceeded with The annual report showed that during the year 7879 patients had been treated, of whom 439 were in patients The total receipts for the year were £3080 of which £733 came from regular annual subscribers, £458 from the contributions of patients, and £310 from the St Vincent s Ball The expenditure was £2921, so that the year's operations reduced the bank overdraft to £533. Subsequently it was decided to form a league to collect the funds necessary for the building of the new hospital

Addenda from the Thirteenth Session and an Index. Vols. I.—XIV., inclusive. Edited by Walter Lester Carr, M.D. Price not stated.

Wright, John, and Co., Bristol.

The Swedish System of Physical Education: its Medical and General Aspects. Expanded from a Paper read before Members of the British Medical Association. By Theodora Johnson, Principal of the Swedish Institute, Clifton, Bristol. Second edition. Reprint. Price not stated.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward to THE LANCET *Office, directed to the Sub Editor, not later than 9 o'clock on the Thursday morning of each week, such information for gratuitous publication.*

Bacque, William Jules, L.R.C.P. Lond., M.R.C.S., has been appointed Medical Officer for the No. 2 District by the Bath Board of Guardians.

Bowlby, Anthony A., C.M.G., has been elected Surgeon to St. Bartholomew's Hospital

Boycott, A. E., M.B., M.Ch. Oxon., has been appointed Gordon Lecturer in Experimental Pathology to Guy's Hospital Medical School.

Edwards, Robert Thos., M.R.C.S., L.R.C.P., has been appointed Resident Medical Officer to the Aberystwyth Infirmary and the Cardiganshire General Hospital.

Flynn, Ignatius Joseph, M.D. Irel., has been appointed Officer of Health at Bunbury, West Australia.

Harris, John, M.D. Aberd., J.P., has been appointed a Member of the Licensing Court for the District of Newcastle, New South Wales, Australia.

Henry, Claud Dawson, M.B., B.S. Camb., has been appointed Police Surgeon at Wellington, New Zealand.

Knight, Wilfred, M.B., L.R.C.P.E., has been appointed a Resident Medical Officer to the Durban Hospital, Natal.

Llewellyn, Rees Frank, M.B., M.Ch. Syd., has been appointed Government Medical Officer and Vaccinator at Braidwood, New South Wales, Australia.

Mould, G. W., M.R.C.S., L.S.A., has been appointed Consulting Medical Officer and Superintendent of the Welsh houses connected with the Royal Asylum, Cheadle.

Mould, Philip G., M.R.C.S., L.R.C.P. Lond., has been appointed *Second Assistant Medical Officer, Royal Asylum, Cheadle.*

Nash, Hon. J. B., M.D. Edin., M.L.C., has been appointed a Director of the Sydney Hospital, New South Wales, Australia.

Parkhurst, Arthur Usk, L.S.A. Lond., has been appointed Junior House Surgeon at the Carnarvon Hospital, Kimberley.

Rennie, G. E., M.D. Lond., has been appointed Director of the Carrington Hospital, Camden, New South Wales, Australia.

Sankey, R. H., M.A. Oxon., M.R.C.S., L.R.C.P. Lond., has been appointed House Physician to the Radcliffe Infirmary, Oxford.

Scowcroft, Walter, M.R.C.S., L.R.C.P. Irel., has been appointed Resident Superintendent of the Royal Asylum, Cheadle.

Scurfield, Harold, M.D. Edin., has been appointed Medical Officer of Health for the City of Sheffield.

Smyth, S. R., L.R.C.S.I., L.K.Q.C.P.I., has been appointed District Medical Officer and Public Vaccinator at Moora, West Australia.

Stiff, H. H., M.B., B.C. Cantab., has been appointed Certifying Surgeon under the Factory and Workshops Act for the Bury St. Edmunds District of the County of Suffolk.

Sutcliffe, John, M.R.C.S., L.R.C.P. Edin., has been appointed Senior Assistant Medical Officer, Royal Asylum, Cheadle.

Waterhouse, A. T., M.B., B.Ch. Oxon., L.R.C.P. Lond., M.R.C.S., has been appointed House Surgeon to the Radcliffe Infirmary, Oxford.

West, Samuel, M.D. Oxon., has been elected Physician to St. Bartholomew's Hospital.

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement (see Index).

Birkenhead Union Infirmary, Workhouse, and Sanatorium.—Resident Assistant Medical Officer. Salary £120 per annum, with board, washing, and apartments.

Bridgnorth and South Shropshire Infirmary.—House Surgeon. Salary £100, with board and lodgings.

British Home and Hospital for Incurables, Streatham, S.W.—Medical Officer. Salary £120 per annum.

Cardiff Infirmary.—Assistant House Surgeon. Also Assistant House Physician. Each for six months. Salaries at rate of £75 per annum, with board, washing, and apartments.

Chelsea Hospital, Cale-street, S.W.—First Assistant Medical Officer. Salary £120 a year, rising to £150, with board, apartments, coal, gas, and washing.

Chelsea Hospital for Women, Fulham-road, S.W.—*Physician.*

Cheshire, Royal Asylum, Cheadle.—Third Assistant Medical Officer, unmarried. Salary £150 per annum, with apartments, board, attendance, &c.

Chesterfield Union.—Medical Officer and Public Vaccinator. Salary [illegible] oduce £250 per annum.

D[illegible] **Dispensary.**—House Surgeon, unmarried. [illegible] and lodging.

Evelina Hospital for Sick Children, Southwark.—House Physician and House Surgeon. Salary £80 respectively, with board, residence, and washing. Also Assistant House Surgeon. Salary £70, with board, residence, and washing.

Glasgow District Asylum, Woodilee, Lenzie.—Junior Assistant Medical Officer. Salary £125, with board, lodging, washing, &c.

Gosforth City Asylum, Newcastle-upon-Tyne. Assistant Medical Officer, unmarried. Salary £140 a year, rising to £160, with apartments, board, and laundry.

Hospital for Consumption and Diseases of the Chest, Brompton.—Resident House Physician, for six months. Honorarium of £25.

Hospital for Sick Children, Great Ormond-street, W.C.—House Surgeon, unmarried, for six months. Salary £20, with board and residence.

Hospital for Women, Soho-square, London, W.—House Physician for six months. Salary £30.

Lister Institute of Preventive Medicine, Chelsea-gardens, S.W.—Studentship for Research in the Department of Bacteriology. Value £150.

London County Council.—Medical Officer to employés in the Metropolitan Boroughs of St. Marylebone and Paddington.

South Uist Parish (Northern Division).—Medical Officer. Salary £70.

Sussex County Hospital, Brighton.—House Surgeon, unmarried. Salary £140 per annum, with board and residence.

Taunton and Somerset Hospital, Taunton.—Resident Assistant House Surgeon for six months. Salary at rate of £50 per annum, with board, lodging, and laundry.

Throat Hospital, Golden-square, W.—Resident House Surgeon. Salary £50 per annum, with board, residence, and laundry.

Westminster Hospital.—Assistant Pathologist and Curator of the Museum. Salary 100 guineas a year.

Wolverhampton and Staffordshire General Hospital.—House Physician. Salary £100 per annum, with board, lodging, and washing.

THE Chief Inspector of Factories, Home Office, S.W., gives notice of vacancies for Certifying Surgeons under the Factory Act at Bray, in the county of Wicklow, and at Greenodd, in the county of Lancaster.

Births, Marriages, and Deaths.

BIRTHS.

Byers.—On Oct. 7th, at Dreenagh House, Belfast, the wife of Professor Byers, M.D., of a son.

Vinter.—On Oct. 12th, at Udal Garth, Torpoint, R.S.O., Cornwall, the wife of Sydney G. Vinter, M.R.C.S., of a daughter.

Windsor.—On Oct. 9th, the wife of Charles William Windsor, M.A., M.D. Cantab., Royston, Herts, of a son.

MARRIAGES.

Lock—Graves.—On Oct. 13th, at St. Giles' Church, Cambridge, by the Rev. Canon Cunningham, D.D., Fellow of Trinity College, assisted by the Rev. A. J. Hunter, M.A., rector of Swanton Morley and Rural Dean, and the Rev. J. F. Buxton, M.A., vicar of the parish, John Lewis Lock, M.A., M.B., B.C. Cantab., of Uxbridge, eldest son of the Rev. J. B. Lock, Fellow and Bursar of Caius College, to Beatrice Marion, youngest daughter of the Rev. C. E. Graves, Fellow and Tutor of St. John's College, Cambridge

Mounsey—Russell.—On Oct. 7th, at Sandyford parish church, Glasgow, by the Rev. D. H. Paterson, Airdrie, assisted by the Rev. James A. Campbell, Troqueer, Dumfries, George Harold Mounsey, M.B., C.M. Edin., 49, Calthorpe-road, Edgbaston, Birmingham, to Helen Greenlees, eldest daughter of James Russell, Banker, Airdrie, N.B.

DEATHS.

Symes.—On Oct. 13th, William Sandham Symes, L.R.C.P., L.R.C.S. Irel., of The Terrace, Chesterfield, in his 54th year.

Tuke.—On Oct. 12th, at *St. Thomas's Home, St. Thomas's Hospital*, George J. A. Tuke, Major, R.A.M.C., in his 46th year.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

CORDITE-EATING.

THE October number of the *Journal of the Royal Army Medical Corps* contains an interesting article by Major J. W. Jennings, R A.M.C., on what he believes to be a hitherto unrecorded form of intoxication—namely, cordite eating by soldiers. His attention was first called to the subject during the recent operations in South Africa and as an experiment he tried one fourth of a strand from a Lee-Metford cartridge which he kept in his mouth and sucked for two minutes. On being then taken out its diminution in size was scarcely appreciable and yet he experienced the most racking splitting headache that he ever felt in his life, together with hammering and ringing noises in his ears; the headache lasted quite 36 hours.

Cordite has a sweet, pleasant, pungent taste and is only slightly soluble in the mouth. Its physiological action is similar to, but slower than, amyl nitrite—namely, throbbing headache, flushing of the face, visible carotid pulsation, giddiness, disordered action of the heart, &c. Roughly, its percentage composition may be said to be nitro-glycerine 58 parts, gun cotton 37 parts, and mineral jelly five parts. Acetone is used as the solvent but does not enter largely into its composition. The thick pasty mass is then forced through a die under heavy pressure. Each Lee-Metford cartridge contains 60 cylindrical strands of cordite and each strand measures one and a quarter inches in length and one-twenty-fifth of an inch in thickness. The following train of symptoms are commonly presented by a man who has eaten cordite. The conjunctivæ become of a yellowish tinge and the eyes assume a glazed appearance, giving to the face a wild expression. The features are drawn The skin of the body presents a dirty yellowish or brownish or sallow tint. Constipation and occasional slight fever prevail, periodical or almost constant headaches, loss of appetite, marked thirst, dulling of mental faculties, and great desire to sleep. When taken in stick form (from four to ten or more strands) cordite rapidly produces a violent splitting headache in the temporal and occipital regions, the headache continuing all day.

Taken in solution, as with tea, cordite appears to produce an almost immediate exhilarating effect. If many have partaken of the beverage all begin talking at once, seemingly anxious to inform each other of everything that happened to them since their birth. This condition lasts perhaps two or three hours, when sleep overcomes them. If beer is in addition consumed during the excited state it produces quarrelsomeness and leads to acts of violence. If the cordite is mixed with beer and consumed as an ordinary drink a glassful will produce intoxication in a man who could normally consume perhaps as much as from four to six pints without exhibiting a trace of having done so. From five to ten strands taken with beer or tea produce heavy sleep followed by a stupor lasting approximately from five to 12 hours. While in this state the man is with difficulty awakened or persuaded to rise. The awakening is accompanied by a severe, dull, boring headache, slight facial muscular twitchings, and protrusion of the eyes. When fully awake the man often seems not to realise his surroundings and a question may have to be repeated two or three times before he understands it. Major Jennings gives the two following examples of the extraordinary effects produced by cordite. In consequence of some trouble with the native assistants the caterer of the non-commissioned officers' mess of an irregular cavalry corps had no food ready when supper-time arrived but he nevertheless rang the supper-bell. The men came and took their seats before an empty table, whereupon the caterer told them with the utmost gravity that there was a nice large roast on the table and everything else which constituted a good supper, adding, "I know you can't see, but I can, so dig in." The non-commissioned officers made their supper off some tinned food which the canteen sergeant provided and the caterer slept the sleep of cordite. In another case a dozen or more men having taken their usual dose of beer and cordite were all talking and shouting at once, when one of them proposed a war dance. It was a still though bitterly cold night and the men were in their underclothing. In spite of this they took their candles outside their tents, placed them upon the ground, and proceeded to execute a series of antics which clearly indicated them to be under the influence of some drug. No amount of persuasion on the part of the non-commissioned officers or anyone else had any effect on them. They kept it up for 20 minutes or half an hour until they sank exhausted on the ground. In his article Major Jennings quotes at considerable length a series of statements made both to him and to Lieutenant Morton, R.A.M C, by soldiers who had been eating cordite.

WANTED—A PLACE FOR AN UNQUALIFIED ASSISTANT.

"X. Y. Z." writes:—

> "Can you give me any advice as to getting employment for an excellent assistant who has been with me 17 years and now is refused situations because he is 60 years of age? He is a married man and leaves me because I have now a partner."

The General Medical Council has clearly defined the uses to which it is permissible to put unqualified assistants and by so doing has made the demand for their aid very limited. We have always felt very sympathetic towards the men who were thus thrown out of employ, even while we recognised that the action of the General Medical Council was good and taken in the interests of the medical profession and public alike. If, however, a medical man is looking for an unqualified assistant we think that 17 years of excellent character held by "X. Y. Z.'s" late employé might well counterbalance his weight of years. After all, a man of 60 has many years of good work left in him, and it is quite likely that anyone who accepted this veteran's services might find that in doing a kind action he had benefited himself.

THE WILLIAM CADGE MEMORIAL.

IN THE LANCET of Sept. 26th, p. 893, we published an appeal for subscriptions towards the erection of a memorial to be placed in the cathedral at Norwich to the memory of the late Mr. William Cadge. The following is a list of those who have already responded to the appeal:—

LONDON.—
Lord Lister.
Sir William H. Broadbent, Bart., K C.V.O.
Sir Thomas Smith, Bart., K.C.V.O.
Sir Anderson Critchett.
Sir Henry G. Howse.
Sir Hugh R. Beevor.
Mr. Jonathan Hutchinson
Mr. Reginald Harrison.
Mr. Christopher Heath.
Mrs. E. Garrett Anderson
Mr. Rickman J. Godlee.
Mr. A. Pearce Gould.
Dr. Robert Barnes.
Professor Howard Marsh.
Mr John Langton.
Mr. H. T. Butlin.
Mr. A. W. Mayo Robson.
Brigade-Surgeon Lieutenant-Colonel D. T. Keegan, I.M.S. (retired).
Dr. H. Charlton Bastian.
Dr Constantine Holman.
Dr. John H. Galton.
Dr. Ernest W. White.
Dr. E. A. White.
Dr. T. Duka
Mr. G. S. Bates.
Dr. Charles Firth, Gravesend.
Dr. Dudley W. Buxton.
Mr. A. E. J. Barker.
Mr. H. Work Dodd.

NORWICH:—
Sir Peter Eade.
Sir Frederic Bateman.
Dr M. Beverley.
Dr. S. J. Barton
Mr. H. S. Robinson.
Mr. S. H. Burton.
Dr. S. H. Long.
Dr. F. W. Burton-Fanning.
Mr. Donald D. Day.
Mr. H. A. Ballance.
Mr. W. H. Day.
Mr. Charles E. Muriel.
Mr. Joseph Allen.
Mr. F. Long.
Mr. G R. Master.
Mr. H. C. Nance.
Mr. T H. Morse.
Dr. J. Fielding.
Dr. H. Watson.
Mr. F. Preston.
Dr. H. Cooper Pattin.
Mr H. F. White.
Mr. E. W Everett.
Mr. H. Watson Turner.

NORFOLK:—
Mr. Mayo Yarmouth.
Mr. W E. Wyllys, "
Mr. W. J. Wyllys, "
[illegible]
ham.
Mr. W. E. Soffe, Scarning.
Dr. T. B. Dyer, Brundall.
Dr. Pembroke R. J. B. Minns, Thetford.
[illegible]
Dr. C. A. O. Owens, Long Stratton.
Mr. F. Clowes, Stalham.
Dr. S. Hamill, Burnham Market.

SUFFOLK—
Mr. F S. Worthington, Lowestoft.
Mr. J. C. Worthington, "
Mr. H. B. Walker, "
[illegible]
Dr. [illegible], Ipswich.
Dr. J. C. Thresh, Chelmsford, Essex.
Professor John Chiene, C.B., Edinburgh.
Mr. T. W. Drinkwater, Edinburgh.
Professor T. Clifford Allbutt, Cambridge.
[illegible]
Dr. [illegible], Weymouth.
Dr. H Briggs, Southport.
Dr Walker, Peterborough.
Dr. Bridgwater, Uckfield.

The list will be closed at the end of this month. Subscriptions may be sent to Dr. M. Beverley, Norwich.

THE MOTHER'S FRIEND.

MR. S. BRIGHOUSE concluded an inquest at Earlestown on Sept. 29th upon the body of the seven weeks old son of a joiner and his wife who met with his death in the following circumstances. The baby was ailing and the grandmother having diagnosed the cause of his trouble as "wind" sent a sister of the child's mother to buy "two pennyworth of Mother's Friend." Evidence was given by a druggist from whom the family in question usually purchased it that "Mother's Friend" was sold by every druggist in the town and that they all made it up differently. It was also known as "Infant's Preservative," "Children's Mixture" and "Infant's Cordial." He for his part when asked for "Mother's Friend" sold a mixture containing one grain of bicarbonate of potassium, one grain of bromide of sodium, and water, flavoured with aniseed. On the occasion in question, however, the aunt of the deceased not being directed to go to any particular shop went to the nearest at hand, kept by a Mrs. Mee. Mrs. Mee was out but Mr. Mee took the bottle which had

Communications, Letters, &c., have been received from—

A.—M. J. Astier, Asnières, France; Messrs. Allen and Hanburys, Lond.; Achates; A. P. B. E., Dr. B. Anningson, Cambridge; Mr. Walter Asten, Horbury; Association of Physicians and Surgeons of the Society of Apothecaries, Oxford, Treasurer and *Acting Secretary of.*

The Harveian Oration

ON

THE STUDY OF STRUCTURE IN RELATION TO FUNCTION.

Delivered before the Royal College of Physicians of London on Oct. 19th, 1903,

By W. H. ALLCHIN, M.D. Lond.,

FELLOW AND CENSOR OF THE COLLEGE; SENIOR PHYSICIAN TO THE WESTMINSTER HOSPITAL.

Mr. President, Fellows of the College, and Gentlemen,—In proceeding to discharge the duty which you, Sir, have laid upon me, and for which honour I desire to express my grateful appreciation, my course is in great measure laid down for me by the injunctions of the illustrious Fellow of this College whom we meet to-day especially to commemorate. In the deed by which he conveyed to the College in 1656, a year before his death, his estate at Burmarsh in Kent, Harvey provided that: "There shall be once every year a general Feast for all the Fellows; and on the day when such Feast shall be kept some one person of the said College shall be from time to time appointed, ... who shall make an Oration in Latin publicly in the said College, wherein shall be a commemoration of all the benefactors of the said College by name, and what in particular they have done for the benefit of the said College with an exhortation to others to imitate those benefactors and to contribute their endeavours for the advancement of the Society according to the example of those benefactors; and with an exhortation to the Fellows and Members of the said College to search and study out the secrets of Nature by way of experiment, and also for the honour of the profession to continue in mutual love and affection amongst themselves without which neither the dignity of the College can be preserved nor yet particular men receive that benefit by their admission into this College which they might expect; ever remembering that concordiâ res parvae crescunt, discordiâ magnae dilabuntur." Herein may be read the whole duty of the Harveian orator and I might occupy my hour and your attention on this, the 247th anniversary, by a recapitulation of those who have materially benefited the College by their gifts and endowments, as well as of those who by precept and example have added to the lustre of our College and have benefited mankind by their pursuance of Harvey's exhortation "to search out the secrets of nature." Not a few of my predecessors in this honourable office have with much learning and in graceful diction fulfilled their task thus; as others have preferred to consider some aspect of Harvey's work in the light of more modern knowledge; or to show how fruitful have been the methods inculcated by Bacon, which Harvey was one of the first to apply, in extending the domain of science in those branches more closely associated with our own. Others, again, have pictured for us in eloquent phrase the times in which Harvey lived and have called up to our appreciation his companions and contemporaries and the influence they exerted on the thought and progress of his age. And in this brief survey of how the theme has been treated it would ill become me to omit a reference to the masterly oration of our learned Harveian librarian who sought to show in true light the relation of Harvey to his great predecessor Galen and how mistaken some of the notions concerning that relation have been. Further, too, he has pointed out that notwithstanding a large amount of very faulty anatomical knowledge that was considerably corrected by the seventeenth century, "Galen's sources of evidence respecting the motion of the heart were the same as Harvey's—viz, comparison of structure in a variety of animals, argument from the use of these structures, observation of the living heart, and numerous experiments on animals."[1]

I am not concerned, even were it needful, again to tell the oft-told tale of Harvey's great discovery and how he demonstrated the truth thereof, for that it was that rendered his epoch-making work the glory that it is; nor yet to defend his claims to the full merits of all he did against the pretensions of those who sought to belittle it or even boldly aimed to usurp what to him alone belonged. This has been done more than once and done completely. Nothing I could say could add one iota to the justification; to attempt it were almost to cast a doubt upon its truth. Briefly would I commemorate the good deeds and the munificence of our founders.

the College in perpetuity his patrimonial estate at Burmarsh in Kent, then valued at £56 per annum." In his will also he thus further testified his affection for the College. "Touching my books and household stuffs, pictures and apparell of which I have not already disposed I give to the College of Physicians all my books and papers, and my best Persian long carpet, and my blue imbroyedyed cushion, one pair of brass irons, with fire shovell and tongues of brasse, for the ornament of the meting room I have erected for that purpose." He further directed Dr. Scarborough and Dr. Ent to select from his library and collections such as "they shall think fit to present to the College and the rest to be sold and with the money buy better."

Passing to the benefactors of more recent date it is my pleasing duty to mention Mrs. Bradshaw, who in 1875 bequeathed £1000 in Consols to found a Lecture to be delivered annually in memory of her husband, Dr. William Wood Bradshaw a Member of this College A similar bequest was made to the Royal College of Surgeons. Dr. Gavin Milroy, a Fellow of this College, who in 1886 bequeathed a sum of £2000 to establish a yearly Lectureship in "State Medicine and Public Hygiene." Mrs. FitzPatrick, who in 1901 gave to the College under the advice of Dr. Norman Moore a sum of £200 to found a Lectureship in "The History of Medicine" in memory of her husband, Dr Thomas FitzPatrick, a learned Member of the College. Also the following donors of sums for the purpose of providing commemorative prizes or medals to be awarded by the President and Council of the College. Dr. Swiney (1844), jointly with the Society of Arts, a triennial prize of a silver cup, value £100, for the best work on Jurisprudence. Dr. Baly (1866) £400 to [illegible] rnate year for distinction in physiology. [illegible] M.D.," and not restricted to British subjects. A sum of over £400 subscribed in memory of Dr. Walter Moxon in 1886 the interest of which provides every third year a gold medal, value £30, for excellence in observation and research in clinical medicine and is not confined to Fellows or Members of the College. In 1895 Sir Hermann Weber generously presented to the College £3000 to found a prize, to be called the "Weber-Parkes prize," in memory of the late Dr. Edmund Parkes, to be awarded for the best essay on the pathology, prevention and treatment of Tuberculosis. And in 1896, due to the suggestion of our Fellow, Dr. Theodore Williams, a sum of £1000 was presented to the College by Captain Edward Wilmot Williams with the [illegible] memory of the late Dr. Francis Bisset Hawki[illegible] Fellow of the College. A gold medal is [illegible] medical practitioner who has advanced sanit[illegible]

Turning now to those whose achievements have enriched not only our College by their reflected lustre, but mankind at large by the benefit conferred and who by their intellectual labours and scientific results have gained for themselves imperishable fame, it would be wearisome and profitless to mention them merely by name. Time does not allow me to record their doings. Yet it were not decent that in the press and rush of the present day the labours of Gilbert and of Glisson, of Willis, of Young who enunciated the undulatory theory of Light, of Sydenham, of Heberden, of William Hunter, of Prout, Bright, Watson, Parkes, Jenner, Gull, Clark, and Reynolds, former Fellows of this College, should be forgotten on this occasion of the commemoration of our benefactors. Excepting such immortal discoveries as Harvey's, discoveries that mark an era and are starting points in knowledge, it is easy from our present standpoint to overlook the help that the advances made by these workers contributed to the general progress nor are those suggestions which proved to be erroneous altogether to be disregarded since in their refutation the right way often became manifest.

These are but some of those whose good deeds, whether in furthering the material prosperity of the College or adding to its reputation, deserve to be remembered as our benefactors. To commemorate, however, all such "by name, and what in particular they have done for the benefit of the College," as I am enjoined to do by Harvey, would be beyond my powers as I fear it would exceed your inclination to listen. But I should ill perform my duty in this connexion did I not "exhort others to imitate these benefactors and to contribute their endeavours for the advancement of the Society."

In attempting to comprehend the full significance of Harvey's great work on the circulation of the blood it must be recollected that he was first and foremost an anatomist, and that although his discovery and its proof were the result of observation of the actual movements of the heart and vessels and of experiments on the living animal it was by his previous knowledge of anatomy that he was enabled clearly to understand what he observed, and the perfection and, indeed, in great measure the feasibility of his experiments depended on his acquaintance with the structure of the organism he was investigating. And although the name of Harvey is for ever linked with a great and far-reaching physiological truth, one not only great in itself but if possible greater in being the starting point of physiology, and as such of a scientific pathology, it was from the anatomist's point of view that he came to enter upon the inquiry which was so fruitful in result. That a sound physiology is essentially dependent upon an accurate [illegible]edge of anatomy was as well understood by Harvey as it is at the present day. "No one," said he, "indeed, has ever rightly ascertained the use or function of a part who has not examined its structure, situation, connexion by means of vessels, and other accidents in various animals and carefully weighed and considered all he has seen." It is further to be remembered that in the early part of the seventeenth century anatomy was a science that, at least so far as the human body was concerned, had reached a very considerable degree of advancement. The teaching of Galen, who first properly appreciated the importance of physiology, full of error as it was, that had held sway for 1400 years was giving way to the more accurate work of Vesalius. His book, "Fabrica Humani Corporis," published in 1543, and his teaching at Padua marked the beginning of a new era in biological science furnishing the account of the structure of the body as a basis upon which a precise physiology was alone possible and from which a rational pathology and medicine could alone develop. The true course being thus entered upon the work was continued by the contemporaries, pupils, and successors of Vesalius, chief amongst whom were Servetus, Realdus Columbus, Fallopius, Cæsalpinus, and Fabricius, the last named being professor at Padua, whose instruction Harvey himself followed for nearly four years after quitting Cambridge in 1598. There, whilst perfecting himself in anatomy, he became more fully acquainted with such views as were held upon the circulation, modifications for the most part of the Galenic doctrine, with such objections thereto and glimpses of the truth as had been foreshadowed by Vesalius and still more even by Servetus who seems at least to have had some idea of the real nature of the pulmonary circulation.

For the first few years after his return to London Harvey appeared to have pursued his anatomical work and especially the dissection of animals. Becoming a Fellow of this College in 1607 and in the next year a physician to St. Bartholomew's Hospital he was in 1615 appointed Lumleian lecturer, the fourth holder of the office. The subject of the lectures was surgery supplemented by public dissections so arranged as to form series of courses extending over six years. But it was as an anatomist that Harvey evidently regarded himself, for in the dedication of his work "De Motu Cordis et Sanguinis" in 1628 "to his very dear friend, Dr. Argent, the excellent and accomplished President of the Royal College of Physicians, and to other learned physicians, his most esteemed colleagues" he concludes thus, "Farewell, most worthy doctors, and think kindly of your anatomist, William Harvey." In the course of the introduction to the same work the author appeals to the similarity of structure of the two ventricles as being in favour of their pursuing a similar function which was contrary to prevailing ideas. And lastly, the final chapter of his "anatomical disquisition" shows how "the motion and circulation of the blood are confirmed from the particulars apparent in the structure of the heart and from those things which dissection unfolds." "Harvey's method of inquiry was that which may be called the purely and strictly physiological method. Observing carefully the phenomena of the living body he sought in the first place, in the arrangements of the structures concerned in the facts of anatomy, for suggestions as to how the phenomena might be explained. It is this aspect of his method which brings into striking light the value of the work of Vesalius and of the school of Vesalius as the necessary preparation for Harvey's labours. Vesalius opened up the way for physiological inquiry by his exact anatomical labours ...... and his successors did little more than widen the way which he had opened up. Harvey was the first who followed up the anatomical path till it led to a great physiological truth. ...... He made no appeal to any knowledge or to any conceptions outside the facts of anatomy and the results of experiments. ...... The patient examination of anatomical features, if possible a comparison of those features in the same organ or part in more animals than one, the laying hold of some explanation of the purpose of those features suggested by the features themselves, and the devising of experiments by vivisection or otherwise which should test the validity of that explanation, that was Harvey's threefold method."[4]

I propose to consider how far the ascertainment of the facts of structure as a necessary preliminary or adjunct to experimental methods has influenced the progress of biological knowledge and what may be the limitations and extensions of the subject in that direction But I would guard myself at the same time from being supposed to assume that anatomy, however complete and precise, is of itself sufficient to furnish a physiology or knowledge of function, since in the earlier days to which I have referred when the facts of gross anatomy were well and widely known most erroneous and grotesque views were held as to the action and uses of the various organs—as indeed, the history of the explanations offered for the circulation of the blood before Harvey's time sufficiently testifies Nor do I fail to admit that much physiology more especially in recent times, has become known even with considerable approach to exactness without a corresponding knowledge of its structural basis The discovery and proof of the circulation, not only by the actual positive knowledge which it furnished, but also by the methods by which it was arrived at, did much to dispel the fanciful and absurd views held as to the other *functions of the body and thus became the starting point of* modern physiology But, as I propose to show by a few examples the full benefit of Harvey's work and indeed its applicability in explaining those other functions, was proportional to the extent of the accurate information possessed in respect to the structure of the organs by which these processes are carried out, and as fresh anatomical know*ledge was forthcoming so did truer conceptions of the living* activities develop from their observation and experimental investigation

---

[4] Lectures on the History of Physiology during the Sixteenth, Seventeenth, and Eighteenth Centuries, by Sir M. Foster, K.C.B., M.D., D.C.L., secretary to the Royal Society. 1901.

The rational study of the respiratory function for example, followed much the same course as did that of the circulation of the blood The Galenic doctrine on this subject was that which Fabricius propounded in the lectures to which Harvey listened The air which was introduced into the lung by the "rough artery"—or, as we call it, trachea—was for the purpose of modifying and regulating the innate heat of the heart, of getting rid of the fuliginous vapours which resulted from this innate heat and further with the object of being conveyed by the "vein like artery" (pulmonary vein) *to the left side of the heart*, there to generate those vital spirits which the arteries carried throughout the body Although Harvey's discovery set aside at once and for ever such unintelligible nonsense as it had upset the corresponding views of the heart's action, the time was not yet quite ripe for laying the foundation of sounder principles as to the function of respiration The *state of knowledge of the anatomy of the lungs* was scarcely as far developed in Harvey's time as was that of the structure of the heart, as may be seen in the "Mannuall of the *Anatomy or Dissection of the Body of Man*" (enlarged 1642) by Alexander Read, who was a Fellow of this College as well as "Brother of the Worshipfull Company of the Barber Chirurgions"

Moreover, the significance of the movements of the chest in breathing and of their relation to the entrance and exit of the air from the lungs was but imperfectly realised If to Borelli may be attributed the first settlement of these questions on right lines, applying as he did to the problem the growing mechanical and chemical knowledge of his day, and showing as he did that the air entered the lungs as a result of atmospheric pressure as the chest enlarged by muscular contraction and further that the air inspired was actually taken up by the blood and that this was essential to the life of an animal, all of which are the facts which are at the basis of our present knowledge of the subject—if, as I say, Borelli showed this the way for his so doing was made clear for him by what had been done in explaining the true structure of muscular tissues and still more by the labours of his fellow professor at Pisa Malpighi More than 50 years after the invention of the compound microscope this observer applied it to the investigation of the tissues and had himself informed Borelli of the minute structure of the lungs how the terminal branches of the air tubes ended in closed vesicles on the walls of which the smallest blood vessels ramified forming the communication between the arteries and veins and thus supplying the completing link to Harvey's work within a few years after our great countryman's death On such a foundation of exact knowledge the further pursuance of the subject was one for the physicist and chemist and by them it has been brought to a high pitch when once the nature of the machine they had to deal with was clearly defined. Observation and experiment were profitably occupied when anatomy had cleared the ground

It was not only with the functions of respiration that Malpighi's great work on the investigation of tissue structure was concerned His labours, added to and developed by the famous Dutchmen van Leeuenhock and Swammerdam as well as by the Englishman Robert Hooke, rendered possible the satisfactory examination of the other functions, though the difficulties of the necessary observation and experiment were greater than they were in respect to the circulation and respiration. Connected with the latter, questions of a mechanical and chemical character arose more capable of being answered as the sciences of physics and chemistry were at the time being better understood While it was comparatively easy to see the movements of the heart and of the lungs in a living animal when these organs were exposed, vivisection did not render so clear the secretory activities of the glands, the changes brought about by digestion, the intricacies of tissue nutrition, and the workings of the nervous system These physiological problems were more intimately connected with the living material and were not so open to such observation or experi*mental inquiry* as was then *possible* *And it may be said* that less even was known of the structure of the organs concerned in these functions than there was of the circulatory and respiratory systems But Malpighi and his fellows showed the way to what was wanted, and as will appear the uses and workings of the structures became open to scientific inquiry with important consequences

Mention must be made, however, in further illustration of my theme of what had been done to provide truer conceptions of the nature of *muscular action* Up to the time of Vesalius and even *for some time afterwards*, the contractile power of the muscles was regarded as resident in the connective tissue sheath of the fibres, the true muscle substances being looked upon as packing Vesalius first indicated the proper rôle of this material, but it was not until more than a century later, in 1664, that Nicolas Stensen, a Dane, described (1664-67) the structure of muscular tissue as he had studied it with the microscope, and thus furnished Borelli with the anatomical grounds upon which he formulated the principles of the action of this substance, also showing that *the contractions were induced through* the nerves Although much that he taught was erroneous, being entirely dominated by mechanical conceptions of the nature of muscular contractility, the refutation of his errors showed the right lines, which was possible only on the structural basis which the microscope had supplied The most important step towards an understanding of the nature of muscular action was *taken shortly afterwards by a Fellow* of this College, Francis Glisson, whose name is more generally associated with his work on the liver and on rickets. In a treatise however, published by him in 1673, "De Natura Substantiæ Energetica" he first explained the property of muscle substance which he called irritability, the character and phenomena of which were further developed by Haller nearly a century later

Important as was the work that Malpighi did in respect to the discovery of the capillary blood-vessels and the structure of the lungs, almost if not quite as great was that which he accomplished in connexion with the *secreting glands* In earlier times the word "gland" had a wider range of meaning and included *such organs as the brain and tongue* That some of them were concerned in straining off certain serosities or humours from the blood was also generally held, but the active agents in the process were quite unknown as would naturally be the case when the intimate structure of the organs was hidden from view To the nerves this function was often attributed, but the physiology of secretion was on a par with that of the heart or the lungs, with which, of course, it was interwoven Within a few years previous to the time that Malpighi was investigating the structure of *the skin, the liver, and the kidneys, the* ducts of the pancreas and of the submaxillary and parotid glands were discovered and the position of these organs as secreting glands recognised Malpighi, in addition, showed the lobular structure of the liver and the relation of the acini to the blood vessels, and showed the general course and arrangements of the renal tubules and of the glomeruli and capsules which were named after him The instruments at his disposal did not permit him to realise the cellular constituents of these several organs, but all these researches gave the *death blow to the older conceptions as to the part* played by the nerves in the secretory processes and it was realised that the secretions were derived from the blood in its passage through the glands and were passed into the commencements of the ducts Stensen, indeed, who had discovered the submaxillary duct, seems to have had a foreshadowing of the vaso motor influence on secretion

The subject of *digestion* need not detain me; the problems with which it is concerned are so essentially chemical in nature that although in the latter part of Harvey's period and within a few years after the existence of the digestive juices as secretions of the various glands was known, their composition and mode of action on the foodstuffs were not a matter of anatomical inquiry and depended for their satisfactory investigation upon a knowledge of chemistry that was developed altogether outside the study of the living body.

Of all the functions of the body none, it would be at once admitted, is more difficult of study or more obscure in the investigation than that of the *nervous system*. None also has been the subject of cruder description or wilder explanations. That this is so would seem natural, clearly associated as nervous phenomena are with the more recondite phenomena of life and subject as their study has ever been to the influences of metaphysical speculation. At the same time, however, one, and as I conceive the most important, circumstance that has retarded the rational development of neurology has been the extreme difficulty that has existed in obtaining a precise knowledge of the actual structure of the organs which subserve the function. Even at the present day, great as are the advances that have been made, I think I should be correct in saying that less is known of the minute anatomy of the nervous centres than of any other organs in the body. Whilst it may be said that with the present means at our command a knowledge of the histology of many of the tissues has reached or almost reached its limits, the precise disposition of the multiplicity of nerves and cells that constitute the brain and spinal cord as well as the ultimate termination of the nerve fibrils in the tissues and in the centres are yet to seek. Hence it is that whilst during the period of Harvey and immediately subsequently the study of the several functions to which I have referred began to emerge from the erroneous and fanciful notions by which they were surrounded and their investigation to be started upon lines that have been followed to the present day, the phenomena of the nervous system for some time remained enveloped in the mystic obscurity that had enshrouded them with growing intensity from the earliest times, an obscurity that was if possible made greater by the lengthy and unintelligible phrases in which they were described.

The main divisions of the brain were recognised—cerebrum and cerebellum, medulla, corpus callosum, corpora striata, ventricles, and even such smaller parts as the corpora geniculata, pituitary body, pineal gland, infundibulum, and septum lucidum. The distinction into white and grey matter was also appreciated, and that the former was made up of fibres was supposed. But the structural relation of the several parts to one another was very indistinctly realised, and anything further as to minute structure was, of course, unknown. The following extract from Read's Mannuall of Anatomy, already mentioned, will serve to show what was taught in a standard text-book, as we should now call it, concerning the functions of the brain.

> Of the action of the brain. The action of the brain is this: After that the spirits and blood are discharged into the Sinus of the dura mater by the veines and arteries to temper the heat of them the brain is *ordained* (seeing it is colder than the heart) that the animall functions, which are feeling and moving may be the more readily executed. Wherefore the animall spirits seem not to differ from the vitall spirits in substance, but in qualities; viz. the temperament and attenuation; for they must be more temperate because heat doth both taint the reasons (as we may see in drunkennesse and raving) and hindereth or preventeth the motion. The spirits ought also to be more subtile because they are to passe like a thunder through the bodies of the nerves. So, as the vitall spirits are carried to the parts of the bodies by the arteries, so the animall are carried by the nerves. The animall spirits for this cause also ought to be subtill because the *reasonable soul is resident in the brain, which doth contemplate things* immateriall, as angels and it selfe.

Although this may be taken as illustrating the teaching of the day, and the work of Willis "De Cerebri Anatome" (1659) was no advance thereon, there appeared ten years later (1669) a treatise on the anatomy of the brain by Nicolas Stensen, whose investigations on secretions have already been referred to, which foreshadowed in several respects many of the discoveries made and views held a century and more later. But the special feature of this treatise as bearing on my present subject is that after pointing out the extremely slight information possessed as to the essential structures of the nervous system Stensen refused to admit, in face of the lack of all sound anatomical knowledge, any physiological deductions whatever. After pointing out a number of cases in which he shows that adequate anatomical knowledge is wanting he says, "Whence you may guess how little trust is to be put in explanations based on such a futile foundation." "I have said nothing of the use of parts, nothing of the actions which we call animal, since it is impossible to explain the movements carried out by a machine so long as we remain ignorant of the structure of its parts."[5] It was only very gradually that this ignorance was cleared up, and pending that the progress of neurology was hindered by the mystical speculations of successive metaphysical doctrines. Until the discovery of the nerve cells and their connexion with the fibres was made in the fourth decade of the last century no very sound notions on nervous function were possible.

Slowly and with many throw-backs as physiology emerged from obscurity and became established on a scientific basis the correlative subject of pathology long lagged behind in taking up a similar position. The reluctance, as it were, to regard morbid processes in the same manner as those manifested by a healthy organism was no doubt in part responsible for the delay in establishing any clear conceptions as to the nature of disease, but what was of far greater influence was the lack of any systematic observations on the appearances presented after death, anything that, in short, might be looked upon as a knowledge of morbid anatomy. Hence it was that the notions respecting disease and its working were, if possible, more fanciful than those held in connexion with the healthy body and were retained for long after the latter had been diverted on to right lines. Although isolated records of post-mortem examinations were made from time to time[6] it was not until the latter half of the eighteenth century that Morgagni laid the foundations of a scientific pathology by his work "De Sedibus et Causis Morborum" (1780) upon which a goodly superstructure was soon erected. "It stands most clearly revealed," says Virchow,[7] "in the history of pathology that the division of the body first into the larger regions (head, breast, abdomen, &c.), then into organs, then into tissues, and finally into cells and cell territories, was the first step which opened up to us the comprehension of disease." There is good ground for thinking that this comprehension would have been sooner grasped if the collection of records of post-mortem inspections which Harvey had made over many years had escaped the destruction which befell many of his papers when his house in London was ransacked during his absence at Oxford with King Charles.

From this necessarily brief sketch of the development of physiology in relation to gross anatomy it is apparent that any approach to an accurate understanding of the working of the several functions was only possible when the facts of structure were ascertained and appreciated and that when these facts were scanty fanciful and erroneous views were entertained as to the mode in which the corresponding functions were performed. With the prosecution of anatomical investigation beyond the range of the unaided vision the knowledge of the living organism and its working was by so much extended. The impetus given to the study of microscopic structure by the labours of Malpighi and his followers resulted in establishing histology—a term first used by Carl Mayer in 1820—as a specific branch of anatomical inquiry which has been pursued with ever-growing success to the present day, coincidently as the realm of gross anatomy became more and more restricted, so far as the human organism is concerned, by the very completeness of the knowledge of it. Did time permit it would not be difficult to show, as indeed has in part already been done, that as the intimate structure of the tissues became revealed, so was the way cleared for a sounder physiology whether by a more rational understanding of what observation and experiment had disclosed or by indicating the direction in which observation and experiment might be fruitfully continued.[8]

The progress of histological research has been marked by one great feature—far-reaching in its effects and of fundamental importance—the recognition of the cell as the tissue unit. And whilst this has served to give completeness to the views of tissue structure and especially of the genetic relations of the several components of the organs, it served as a fresh starting point for the investigation of biological problems, since it was recognised that the life of the organism was but the life of the cell, differing only in degree of completeness; and the full realisation of what is meant by specialisation of function being dependent on differentiation of structure became apparent. With entire appreciation of the complexity of the phenomena presented by the living cell, *Brücke 40 years ago affirmed that this must imply the* existence of some structural arrangement in the cell substance, some degree of organisation, some further stage than had hitherto been detected in the disposition of the material which subserves function. Setting aside the obvious distinction into cell contents nucleus and attraction sphere, and the separation of the first into cell protoplasm and the metabolic products thereof (such as starch, fat, [illegible] on has been [illegible] homogeneous [illegible] rous observers [illegible] this material, a view that later gave place to the assertion that it is rather to be regarded as of a reticular nature, the protoplasm form- [illegible] "the nodal points of which appear [illegible] The imperfect loculi formed by this [illegible] described as being occupied by a more fluid material. Objections were raised to this explanation and the more recent description with which the name of Bütschli is associated attributes to the protoplasm a "foam-structure, which depends upon the presence within a uniform ground mass of a large number of extremely fine vacuoles lying almost at the limit of microscopic visibility, and so close together that their walls consist of relatively thin lamellæ" (Verworn). But these and several other views as to the intimate structure of the living cell protoplasm which describe it "as being composed of two substances, one of which is disposed as a contractile net according to some, as a relatively rigid framework according to others, or as free filaments; or whether it be built up of a more solid material and of a more fluid material which occupies the minute spaces or vacuoles which are hollowed out in the former,"[10] have not met with universal acceptance and there are still those who regard these relatively coarse indications of structure in cells as the results of post- [illegible] To such the living pro [illegible] and its "peculiar and [illegible] ated with molecular rather than with molar structure." What is said as to the cell contents applies also to the nucleus in which a reticular or meshwork appearance is described by some, as others would regard the actual living condition as one of [illegible] question of the intimate struc- [illegible] lasm must at present be left, so [illegible] investigation by the microscope and its accessories. But whilst fully recognising that with further improvments in method and in means this problem will be solved, it none the less seems certain, consistently [illegible] as to the nature of the cosmos, [illegible] be able to penetrate there will [illegible] d a molecular or atomic structure for the understanding of which other branches of scientific inquiry must be employed. "The organism," says Virchow, "is not an individual but a social mechanism. An exact anatomical analysis of this mechanism always brings us at last to cells; they are the ultimate constituents of all tissues as they were their origins. Hence we call them the living elements and hence we regard them as the anatomical basis of all biological analysis, whether it has a physiological or a pathological object in view. The cells are composed of organic chemical substances which are not themselves alive but the mechanical arrangement of which determines the direction and power of their activity."[11]

[5] Foster: loc. cit., p. 280.

[6] Bonetus in 1675 had collected from previous writers many such in his "Sepulchretum."

[7] Huxley Lecture, delivered at Charing Cross Hospital on Oct. 3rd, 1898.

[8] In the record of histological advance mention must be made of Haller's "Elementa Physiologiæ" (1757), which first presented in a collected form the most correct information on the structure of the tissues, and of Bichat's "Anatomie Genérale" (1801), a still more comprehensive work on the same lines in which also the foreshadowing of the cellular nature of the tissues, established by Schwann in 1838, was faintly indicated, although the word "cell" was not used. To the labours of John Goodsir, and still more to the epoch-making work of Virchow on Cellular Pathology (1858), must be ascribed the demonstration of the fact that our conceptions of morbid processes must be founded on a histological basis—a doctrine that the great pathologist's "Archiv fur Pathologische Anatomie und Physiologie und fur Klinische Medizin" has for nearly half a century constantly expounded.

Before proceeding to consider the next and chemical stage of structure it would be well shortly to indicate some of the living phenomena which have either already received or still await their explanation in the intimate histology of the cell. Most important of these is contractility, whether this [illegible] more diffluent portions into and out of the reticulum of the spongio-plasm—the "streaming," as it has been termed—is a step towards explaining—apart altogether from the attempt to express protoplasmic movement in terms of inorganic phenomena, such as has been done—those alternate contractions and expansions of the bioplasm due to reciprocal rearrangements of its particles which constitute one of the *most striking characteristics of the living organism.* The complicated changes connected with nuclear division known as "mitosis," which underlie all cell multiplication and hence are [illegible] only realis [illegible] which ha [illegible] organisati [illegible] problems of heredity connected therewith can only be discussed in terms of cell structure with any probability of satisfactory results. Possibly also the varied morphological characters presented by the fully developed living constituents of the tissues, developed as they have been through successive stages from cells of almost identical appearance in the blastoderm, may be more fully understood when the structure of their protoplasm is more accurately known. The so-called specificity of cells and its limitations—metaplastic interchanges—so important in the study of tumour formation is an aspect of this same question.

From the earliest recorded times there has prevailed an idea which ascribed to matter an ultimate composition of indivisible indestructible particles or atoms and by no one was the atomic theory more firmly maintained than by the contemporary of the later years of Harvey—Isaac Newton. "To me," said he, "it seems probable that God in the beginning formed matter in the solid, massy, hard, impenetrable particles of such sizes and figures and with such other properties and in such proportion as most conduced to the end for which He formed them." By Robert Boyle also, to whom natural philosophy in the seventeenth century owed much, the theory was held, though he found the explanation of chemical changes in the differences of atomic structure and arrangement of one single form of matter rather than of different elements—a crude foreshadowing of the present-day conception by Sir William Crookes of the fundamental matter or "protyle." As is well known, however, it was not until the early years of the last century that the atomic theory received its practical development by John Dalton, since when it has remained at the foundation of physical and chemical science. "Despite attacks and criticisms," says Professor Clarke in his recent Wilde Lecture,[12] "Dalton's generalisation still holds the field and from it, as from a parent stem, spring nearly all the other accepted theories of chemistry." The conception of an atom as the smallest conceivable portion into which an element can be divided or that can enter into combination, and attaching to the idea of the atom a definite relative weight constant for atoms of the same element but differing with different elements, gave a satisfactory explanation for the laws of definite proportions and of multiple proportions which previously had been but incompletely recognised.

Since, with the exception of a few elementary gases, an atom is always combined with one or more atoms of the same or of other elements, some term is required to denote the smallest portion of the substance capable of a separate existence and for this the word "molecule" is employed. Built up on these fundamental ideas there has developed among other great generalisations the chemistry of the carbon compounds and the hypothetical recognition of the relative arrangements of the atoms within the molecule—in short, chemical constitution or chemical structure. Now "the greater the valency of an element the more complicated are its combining ratios and the greater the possibility of its atoms forming numerous compounds with similar and dissimilar atoms." The atoms of carbon, which is the chief element in so-called organic bodies, "possess, in a much greater degree than those of any other element, the property of combining with similar atoms whereby a part of their valencies are satisfied."[13] Thus may be formed groups

[11] Huxley Lecture.

[12] Delivered on May 19th, 1903, to the Manchester Literary and Philosophical Society on the occasion of the Dalton centenary celebrations.

[13] Principles of General Organic Chemistry, Professor Hjelt, 1890.

of carbon atoms so linked together that their valencies are in part satisfied among themselves, constituting what are known as carbon nuclei, and the free valencies being satisfied by atoms of other elements molecules are formed in which much energy is accumulated with more or less instability. Such conceptions as to the fundamental nature of matter, of its molecular structure and arrangement of atoms therein, permitted the laying down of rational or structural formulæ for chemical compounds, and when the further suggestion was made of linking the atoms in tridimensional space rather than in a single plane a still further extension of the idea of the atomic disposition within the molecule became possible and "stereo-chemistry was born" (Clarke). With theories of this kind ready at hand—theories which had done and are still doing so much to explain the phenomena met with in the domains of physics and chemistry—what more natural than that the biologist, recognising that but little progress was being made in the further investigation of the intimate cell structure and that the histologist in point of fact was apparently at the limit of his range of observation, should turn to the physico-chemical sciences for the satisfaction of his quest?

The attempts, however, from the chemical side to explain the constitution of living matter, due no doubt to the extreme complexity of the subject, cannot be said as yet to have led to any very definite result, although several very suggestive hypotheses have been put forward. Inasmuch as no empirical formula has up to the present been constructed for any one of the typical proteids, a rational or structural formula for the constitution of the undoubtedly large molecules of which these substances are composed is scarcely to be expected, and this, although necessary, is but only the first stage in the inquiry. Analysis of proteid bodies gives rise to numerous products; the end substances, such as carbonic acid, water, and urea, we are familiar with, but the intermediate ones "fall into two principal groups, the fatty compounds (generally containing an amidogen radicle) and the aromatic compounds or derivatives of benzene."[14] Accurate as further work in this direction may become, however, it still of necessity will not be a satisfactory explanation of the composition of living protoplasm which is ever in a state of flux, the continuous decompositions and reconstructions of which underlie its activities—are indeed phases of its living. Hitherto all attempts to ascertain the composition of the bioplasm have resulted in killing the material and hence the solution of the question is evaded. And although proteids are obtained from living protoplasm there is no proof that they exist as such in the living matter but rather are they the dead derivatives of what is killed in the process of examination.

Theories of the constitution of proteids arrived at by the attempted synthesis of these substances have been provisionally set out, and though no one of them is free from objection it may reasonably be supposed that, consistent with prevailing chemical theories, they are on the right lines. Among these should be mentioned that propounded by our distinguished Fellow, Dr. P. W. Latham, according to which, what he terms "living proteid" is composed of a chain of cyan-alcohols and a thio-alcohol united to a benzene nucleus These cyan-alcohols are exceedingly unstable and prone to undergo intramolecular changes, properties also possessed in a marked degree by bioplasm, and similar bodies are obtained from the disintegration of both cyan-alcohols and proteids. A more recent attempt in the same direction has been made by Verworn,[15] who describes the "biogens," as he terms them, as real chemical and physical entities, each consisting of a benzene nucleus round which are arranged various groups of atoms, the idea being arrived at by a study of the metabolic products of the organism. The extreme lability of the biogen Verworn attributes to the incorporation of oxygen in the molecule, the absence of which, rather than the accumulation of waste products, he regards as responsible for the cessation of the irritability of the bioplasm. It may be further observed that it is in the cell protoplasm and not in the nucleus that this observer locates the biogens.

Whilst fully realising the purely speculative character of these conceptions the provisional use that they may be in comprehending the activities of the living organism is apparent. For many of these complex processes the knowledge of the chemical anatomy of bioplasm is as essential as the gross anatomy of the organs concerned is for an understanding of the circulation of the blood. As the chemist and the physicist find in the atomic theory and its developments an explanation of the properties or functions of the non-living bodies with which they deal, so may the physiologist find in the same assumptions a clue to those even more abstruse functions displayed by living materials and furnish to the pathologist and to the clinical physician those data upon which a fuller realisation of morbid processes may be obtained and sounder principles for their prevention or their treatment be laid down.

Where in the whole range of physiological inquiry is to be found a region into which the observer has less penetrated and where for want of some guidance he is more adrift in the comprehension of what he does recognise than in the complicated region of "nutrition"? And yet how essential for the mere framing of a proper dietary or for an understanding of the protean symptoms collectively denominated "gout" is it that we should be able to form some idea of what becomes of the absorbed foodstuffs, when having undergone some elaboration in the epithelial cells, the hepatic tissues, and the blood through which they have passed they come "within the sphere of influence" of the living cell. What, too, is more important than to be able to attach to the comprehensive term "metabolism" some rational meaning, based upon a knowledge of what actually occurs and what structural arrangements and rearrangements take place within the bioplasm of the tissues? The practical importance of this must be obvious and should prevent the relegation of such questions as I have been discussing as transcendental and of no useful purpose.

One of the greatest and most far-reaching advances in pathology within recent years is undoubtedly the recognition of the part played by micro-organisms in the causation of disease. But the full value of the knowledge gained is not comprised in the detection and cultivation of the specific bacillus, nor yet even in the discovery of the particular toxin which the microbe produces, important as such information is. We require to know how and why these poisons affect the tissues as they do and in order to arrive at that the rational formulæ of these poisons must be known and, what is more, the molecular structure of the living cells upon which the noxious material acts ere we can realise how by some untoward substitution in the atomic arrangement of the living molecule its activities are prejudicially affected. Our treatment of disease by drugs has been forcibly if irreverently described as "pouring substances of which we know little into bodies of which we know less." Pharmacology has done a little towards removing this reproach and that department of it which deals with the relation between the chemical composition and constitution of a substance and its physiological action no doubt lies at the root of all rational drug therapeutics. But no one can assert that so far very much is known in this direction or that there has been much practical outcome of the investigations. This would be quite otherwise, however, if we had a knowledge of the molecular structure of living matter which would show the perversions taking place in disease and indicate the way in which they could be corrected.

The subject of immunity may reasonably be expected to find its interpretation in the ultimate constitution of the tissue elements, as also those at present vague conditions which we are dimly conscious of, represented by such terms as "bodily constitution" and "temperament." So, too, the differences in response on the part of different individuals to the same morbific influence, the variations in the manifestation of what we speak of as the same disease in various persons that lead the sagacious physician to treat the patient and not the malady, and, in brief, those intangible characters, which determine the responsibility of the organism for morbid symptoms as distinct from the injurious agent that we speak of as cause—each and all await their explanation. The factors of the environment which condition the vitality of the tissues are not to be found solely in such external conditions as are commonly comprised in that expression.[16]

[14] Professor Halliburton, M.D., F.R.S., in Professor Schafer's Text-book of Physiology, vol. i., p. 35.

[15] Die Biogen-hypothese. 1903. See also Nature, Feb. 26th, 1903.

[16] As illustrating these environmental relationships may be mentioned the various forms of taxis or tropism whereby the direction of the movements exhibited by living protoplasm may be influenced. The best known of these is "chemiotaxis" as met with in connexion with some states of leucocytosis, but it is probable that other forms of taxis caused by pressure, gravity, heat, and light also prevail. "The spermatozoon seeks the ovum, and almost everywhere in the living world is led in the right path by the chemiotactic action which the metabolic products of the egg cell exert upon the freely moving sperm cell. ...... Every species of spermatozoon is chemiotactic to the specific substances that characterise the ovum of the corresponding species"

The behaviour of cell to cell, their mutual interactions—cytotaxis—and their physiological resistances the one to another will have to be taken into account in forming any thorough conception of the totality of life, whether healthy or diseased, that an organism presents, and the understanding of such problems cannot be attained until the finite structure of the material concerned be rendered plain or be assumed with such justification as those concepts underlying physico-chemical action at present furnish.[17] May it not also be in this same molecular structure of living matter that will be found the explanation of those phenomena of development and of organic evolution by which the fertilised ovum of two different kinds placed under identical conditions will each attain "to such form and structure as best fit it for its place in nature—processes which cannot be measured or observed by the same methods as are used in the investigation of the phenomena of non-living nature—i.e., by measurements of their time and place relations under varying conditions—in other words, by the method of experiment"[18] which are applicable to other processes of living organisms? "T

account of growth and

by supposing that the

[i e, the union of a number of molecules to form a single molecule] and then of falling into simpler substances once more."[19] Surely I need not plead for the importance of these questions I have set out, an importance that is not merely the concern of the biologist but is that of the practical physician. In the solution of these problems lies widespread benefit to mankind.

Yet, one step further. The atomic theory of the constitution of matter and its developments, although they have *hitherto sufficed for the needs of the chemist who concerns* himself with the decompositions and reconstructions of substances, is not the last word for some, at least, of the most progressive physicists. Is the atom indivisible and finite? has ever been a question that even the most pronounced atomists have asked themselves from time to time, and if the explanation of the recent discoveries that have been made in connexion with radio-activity be correct the answer must be in the negative. Briefly to summarise from this year's Romanes lecture by Sir Oliver Lodge, the most advanced views that physicists are inclined to hold, it may be said that the atom is conceived as consisting of an aggregate of what have been termed corpuscles and further that each atom may have associated with it a definite charge of electricity, atoms of different kinds having multiples of this charge, such an electrically charged atom being termed an "ion." Now the smallest unit of electric charge which itself "possesses the most fundamental and characteristic property of matter—viz, mass or inertia"—is known as an "electron" and the charge with which the atom is possessed consists of a number of these electrons. Within the atom the "electrons are in a state of vigorous motion among themselves." But it has been found that the electrons can be detached from the atom at an electrode and such isolated particles form the cathode rays which when stopped suddenly by a massive obstacle give rise to the so-called Roentgen rays. Hence the electron "is the most definite and fundamental and simple unit which we know of in nature." Whether, however, the electron is to be considered as solely consisting of electrical charge or whether this be associated with a material particle is a moot point. Some hold that the latter is non-existent and that in place of there being two kinds of inertia, which we speak of as material and electrical, the latter alone exists, the atom therefore being "composed solely of electricity." Such a concept of the electrical nature of matter is obviously a more precise expression of the monistic theory, in accord with which matter and energy are but convertible terms. Such a hypothesis suggests also that the various elements as we know them are but "different groupings of one fundamental constituent," the atom of each one consisting of its own special number of electrons, the unity of matter being thus arrived at. Highly speculative as such considerations are they nevertheless find support in electrical phenomena and still further in radio activity of which we have heard so much in connexion with radium and allied substances. This radio-activity "consists in the flinging away with great violence of actual atoms" which exceed in their rate of movement the fastest cannon-ball ever projected. The substance left is also radio-active and successive residues, differing as they do from each other, yet continue to exhibit radio-activity, "and one of the residues so left seems *ultimately to pitch away electrons simply instead of atoms* of matter"—a veritable transmutation of matter. Thus it is supposed that "the massive and extremely complex atoms

able to get into an unstable

isintegrating fall into other

of matter." Yet it appears that as the radio-active substance thus breaks up fresh radio-active matter is as constantly regenerated, possibly, as Lord Kelvin has suggested, from the ethereal waves surrounding the atoms. Even as the atomic and molecular theory was laid hold of to furnish an explanation of the flux of chemical activity which we denominate bioplasm, so have these further speculations on ionic action been pressed into the same service and with some promise, wholly hypothetical as they may be. It is to Professor Loeb of Chicago that we in the

of the ionic theory to physio-

bulk of protoplasm," he writes,[20]

rial, and the physical manifestations of life, such as muscular contraction, protoplasmic motions, and the innervations, are due to changes of the condition of these colloidal solutions. And the reason why the electrical current is the universal form of stimulation is that the particles in colloidal solutions are electrically charged and that *every alteration of the charge of the particles will result in a process of innervation or a contraction or a protoplasmic motion*" Thus nerve action is simply electrical action, negative ions being released where nerve blends with muscle, or where systems of concatenated neurons come into connexion. Ion after ion is precipitated and thus neural conduction takes place.[21] This play of ions is excited or inhibited by the character of the fluids with which the protoplasm is bathed—by the nature, that is, of the ions which these *fluids contain*. Most effective in stimulating protoplasmic action are such substances as sodium salts, as those of lime restrain it, and since such inorganic bodies are among the products of tissue waste it may be that in the ions of metabolism are to be found the causes of that rhythmic tendency to activity which nerve cell and muscle fibre alike exhibit. If normal neuro-muscular action may be thus induced the theory offers a clue to the comprehension of some of the most obscure morbid manifestations of these tissues, for, says Professor Loeb, "that certain ions are capable of bringing about forms of irritability in nerves and muscles which do not exist normally may perhaps furnish the explanation of a certain number of morbid phenomena (neurosis and hysteria) in which the motor and sensory reactions of the patient are modified."

In thus labouring as it may seem the successive phases of structure from the grossly obvious to such as the microscope

---

(Verworn: General Physiology). The effect also of these external agencies as well as others like moisture and the density of the

[17] As bearing upon these and like questions a very large body of there are great varieties in of a uniform character in all even amongst the simplest in behaviour exhibited by different species in response to various reagents clearly demonstrate this. For whilst some are so profoundly affected in their molecular constitution as to succumb on being subjected to certain poisons, others, in no wise differing so far as can be determined by the means at present at our disposal, are quite uninjured. Some kinds of bioplasm appear to have a general high resistance to all chemical agents while others have a high or low resistance to particular agents only; thus nervous tissue, for instance, is readily and injuriously affected by substances—e.g, cocaine or nicotine—to which many protophyta are indifferent Since also many toxic bodies which produce no effect upon dead albumin are yet violently poisonous to that the latter contains in of molecules which undergo ents All this goes to show consists of numerous kinds of compounds many of which are very unstable. Also that not all protoplasm contains the same compounds but that these are dissimilar in different organisms. And further, that not all of the compounds in any protoplasmic body are essential to life, and that we and gradually by a strong ation, or as perimental

May 11th, 1903.

[19] Nature, loc. cit.

[20] American Journal of Physiology, 1901-02.

[21] Philadelphia Medical Journal, March 22nd, 1902.

discloses, and thence to the hypothetical, chemical, and electrical constitution of the material involved, it is not for a moment claimed that the investigation and the observation of functional manifestation have waited for anatomical discovery. In many departments of physiology, notably in that concerned with nerve and muscle and with secretion, a large mass of information has been acquired as the result of carefully devised experiments, whilst but little has been done towards ascertaining the ultimate structure of the tissues concerned—little, that is, beyond what was known a score of years ago or more. But in respect to such tissues as these microscopic examination would seem almost to have reached its limits, and for the complete comprehension of the physico-chemical phenomena more recently ascertained the problem of the chemical and electrical constitution of the muscle or nerve fibre and of the gland cell awaits solution. Though it may be true that "it is quite impossible to attain to a complete knowledge of function without a thorough anatomical analysis" (Huxley), and this it may be added although the observation of function may have led to the study of structure, yet it is clear that "structure" must include a wider range of meaning than hitherto it has been commonly thought to bear and to reach into those regions where observation is conditioned by speculation and where theory has to take the place of demonstrable fact. However true it may be that for a general conception of the physics of the circulation Harvey was beholden to his anatomical knowledge, it is also true that for our later acquired information of the share taken in the movement of the blood by the arteries an acquaintance with the structure of these vessels is necessary, whereby their elasticity and their tone are referred each to its own tissue. The problem that Harvey solved was one that in its broad features was a mechanical one, but it does not end with such information as the gross anatomy of the organs and the histology of the tissues supply. Behind it lie the contraction of the muscular substance of the heart and arteries and the nervous governance of that material, which involve considerations of another character. For the complete understanding of the electrical and chemical changes which are associated with the passage of the nervous stimulus and the muscular response we should require to know what are the underlying molecular rearrangements and alterations in chemical constitution crudely represented by the formation of certain waste products. At this point, I say, precise knowledge fails us and we turn for assistance to theories which have been so helpful in the explanation of the properties of non-living matter, consistent therein with the principle laid down by Mayer half a century ago "to refer both vital and physical phenomena to a common measure."

Whilst I have endeavoured to illustrate with such completeness as my brief time permits the relationship of physiology to anatomy, whether normal or morbid, the general tenour of my remarks will have indicated that when the limits of visibility, even with our most perfect instruments, have been reached the separate investigation of structure and of function no longer becomes possible. The molecular constitution, chemical or electrical, of living matter becomes conceivable only in terms of action, and function and structure are but aspects of each other. No deeper secrets of nature exist to be searched out by observation and experiment than these and none will more benefit mankind in their discovery. To their investigation therefore, in obedience to the precept of Harvey, do I exhort you to turn.

SOCIETY FOR RELIEF OF WIDOWS AND ORPHANS OF MEDICAL MEN.—A quarterly court of the directors of this society was held on Oct. 14th, Mr. Christopher Heath, the President, being in the chair. Three new members were elected, the death of a member was reported, and the resignation of a member was accepted. The death of a widow, aged 87 years, who had been receiving £50 per annum since May, 1890, was announced. Applications for assistance were read from three orphans of a member who died in 1899 and grants at the rate of £12 per annum were made to them. Applications for renewal of grants were made by 53 widows, 16 orphans, and four recipients from the Copeland Fund and £1321 were voted to be distributed among them at the next court subject to the report of the visitors. It was resolved to make the usual present at Christmas to the widows and orphans on the fund—viz., £10 to each widow, £3 to each orphan, and £5 each to the four orphans on the Copeland Fund. The expenses of the quarter were £64 14*s.* 6*d.*

ON THE EFFECT OF PERFORATION OF THE COLON BY SMALL FOREIGN BODIES, ESPECIALLY IN RELATION TO ABSCESS OF AN EPIPLOIC APPENDAGE.[1]

BY J. BLAND-SUTTON, F.R.C.S. ENG.,
SURGEON TO THE CHELSEA HOSPITAL FOR WOMEN AND ASSISTANT SURGEON TO THE MIDDLESEX HOSPITAL.

FEW of us probably realise the variety and amount of material coming under the denomination "foreign bodies" daily ingested with our food. The methods employed in grinding wheat furnish minute angular particles of millstone; small fragments and chips of straw are not uncommon in flour and in bread. Spicules of bone from beef and mutton, birds and rabbits; needle-like bones from fishes; shot from game; loose stoppings from teeth, and even the teeth, true and false, are occasionally swallowed. Chips from metal instruments employed in preparing food, or from the pans and pots used in cooking are sometimes detected in the course of a meal. Small bodies of this kind occupy the alimentary canal more frequently than do pins, needles, tacks, nails, and bristles accidentally swallowed by individuals who, in the course of their work, foolishly use the lips for purposes mainly fulfilled by the fingers. Even these form a distinct class from such gross things as corks, coins, knives, spoons, forks, razors, glass stoppers, &c., swallowed by lunatics and children, or by men and women for sensational gain, or by thieves to avoid detection.

Those who doubt the large number and variety of metal bodies which find their way into grain will receive instruction by visiting a large brewery, for the grain, previously to grinding, passes over a magnetised bar which extracts and retains the pieces of metal. This metallic rubbish is collected and preserved to excite by its amount and variety the astonishment of visitors. (Samples of the pieces of metal retained by the magnet were exhibited to the audience. They consisted of almost all kinds of nails, brads, tacks and screws, wire tags of laces, metal eyelets, dress-hooks, needles, pins, pens, wire, buttons and metal skeletons of buttons, and chips of metal in great variety selected from a peck of metallic rubbish.) With the grosser kinds of foreign bodies this lecture has no concern; my object is to draw attention to a particular effect which arises when a small foreign body perforates the colon, especially in the vicinity of an epiploic appendage. No doubt hundreds of foreign bodies are ingested and egested without causing the least concern to the host, but the frequency with which an anal abscess comes under the surgeon's notice serves to show that many fail to pass harmlessly through the sphincter.

Before endeavouring to explain the manner by which small foreign bodies probably escape safely from the bowel, as well as indicating the very serious mischief which they are liable to cause when retained, it will be necessary to draw attention to some points in the disposition of fat around the colon and especially its relation to the epiploic appendages. In a transverse section of the descending colon from a healthy adult the fat would have such an arrangement as is represented in Fig. 1. The appendix epiploica is, anatomically, a fold of peritoneum filled with fat and its size depends entirely on the amount it contains; the fat of the appendix can be shown by simple dissection to be directly continuous with the subserous fat which normally fills the interspace of the mesocolon and, with care, it is easy to show that the serous investment of the colon reposes on a subserous tissue containing varying proportions of fat throughout that part of the circumference of the gut which receives a peritoneal investment. In the diagrams used to illustrate this lecture no attempt is made to represent the longitudinal bands of the muscular coat.

When a transverse section of the descending colon from a very fat individual is examined the relation of the subserous fat to that of the epiploic appendix and the mesocolon is easily seen. The part of the colon which is most avoided by fat is the middle tænia or longitudinal band; even in very obese individuals this band is rarely obscured.

---

[1] An address delivered to the Nottingham Medico-Chirurgical Society on Oct. 17th, 1903

After mid-life a variant appears occasionally in these transverse sections in the form of a pouch-like diverticulum; it is possible that some of these sacculations, which must not be confounded with normal haustra of the colon, may serve as retreats for some of the mischievous small foreign bodies which are carried into the colon.

FIG. 1.

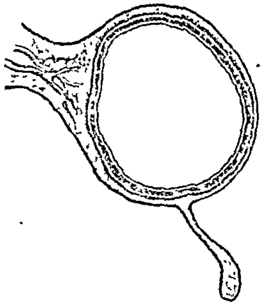

Diagram of a transverse section of the colon from a thin individual, to show the relationship of an epiploic appendix to the subserous fat.

In the specimen from which the diagram, Fig. 2, was prepared one of these sacculi actually appeared in section. It is clear from a consideration of the normal anatomy of the colon that there are portions of its circumference where a sharp foreign body could penetrate and escape into the general peritoneal cavity and the thinner or more emaciated the person the greater is the arc of the gut which would allow this form of penetration. In a fat person, on the other hand, although there is a short arc where it could be easily perforated into the general peritoneal cavity there is a far greater extent of its circumference so protected by fat into which the escaping body would be more probable to find its way and in a certain proportion of cases the penetrating body would lodge in an adjacent epiploic appendix. The fatter the patient the less likely is the foreign body to penetrate into the general peritoneal cavity and the greater is its chance of entering an epiploic appendix.

FIG. 2.

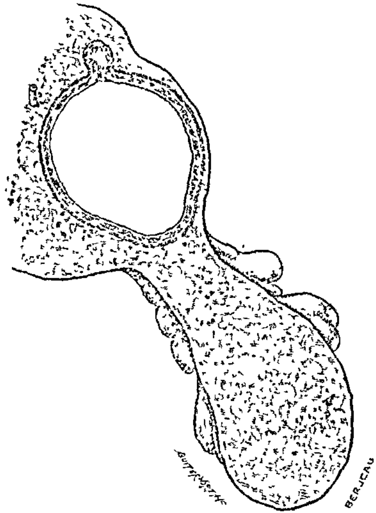

Diagram of a transverse section of the colon from a very fat [illegible]

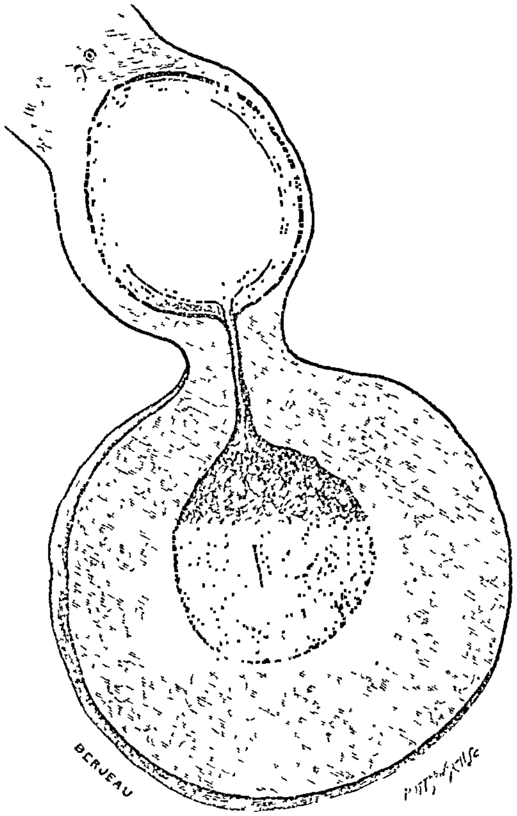
I will now endeavour to prove that foreign bodies from the colon do lodge in the epiploic appendages and to show some of the consequences which arise therefrom.

CASE 1.—On Easter Sunday, 1903, Dr. Edwin Hollings asked me to see a man, aged about 40 years, who had acute pain in the left iliac region accompanied with some local swelling, tenderness, and fever. The signs were such that if they had occurred in connexion with the right instead of the left iliac region a diagnosis of subacute appendicitis would have been irresistible; indeed, the signs were so characteristic of this affection that I made a careful examination to satisfy myself that the patient's viscera were not transposed. We came to the conclusion that he was suffering from an abscess in connexion with the descending colon, probably depending on perforation. We were then informed that he had been accidentally shot in the abdomen many years previously and as the bullet had never been extracted there arose a suspicion in the minds of the patient, his relatives, and medical man that it might be the cause of the present trouble. This view I did not seriously entertain. On the next day Dr. W. Hale White joined us in consultation; he shared our opinion as to the inflammatory nature of the swelling, the almost certain presence of pus, and the advisability of operation. On the following morning I carefully cut through the abdominal wall over the prominent part of the swelling; the line of the incision corresponded as nearly as possible with the lower part of the left linea semilunaris and I tried to find the pus by burrowing behind the peritoneum but without success. I then incised the peritoneum and found an ovoid body as large as a bantam's egg and quite as smooth, sessile on the descending colon. I soon recognised that we had to deal with an enlarged and inflamed epiploic appendix containing a foreign body. I explained this to Dr. Hale White and Dr. Hollings and then split the lump longitudinally with the scalpel. In the centre of the lump there was a distinctly circumscribed cavity communicating with the lumen of the colon by a narrow passage; inspissated fæcal matter filled the cavity and in the midst of it I detected a sharp foreign body. The anterior and posterior halves of the epiploic appendage were secured with silk sutures to the peritoneal edges of the wound, and after inserting a drainage-tube into the fæces-containing cavity the incision was brought together with interrupted sutures of silkworm-gut and dressed with cyanide gauze. About the fourth day fæcal matter escaped freely from the wound; this continued till the tenth day and then the sinus slowly granulated; the patient left London for the seaside at the end of the fifth week.

The relationship of the cavity in the epiploic appendix is [illegible] in Fig. 3. When in the course [illegible] s detected those present at once became alarmed for fear that we had to deal with a tumour of the colon, but I had had an opportunity of operating on a somewhat similar case which led me to study the condition carefully.

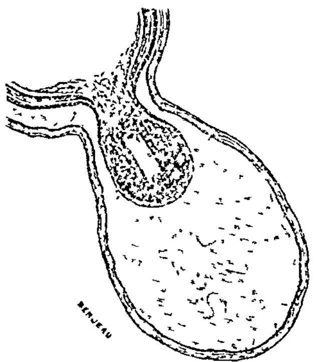
CASE 2.—A spinster lady, about 60 years of age, was placed under my care with symptoms of chronic intestinal obstruction associated with a definite lump of the size of a bantam's egg in the left iliac fossa. The age of the patient, the situation and mobility of the lump, in conjunction with the frequent passage of liquid fæces from the anus, led to the diagnosis of cancer of the descending colon. The lump, however, caused more pain than is usual with cancer of the colon and it was particularly tender—indeed, the pain and tenderness rather than interference with the function of the bowel induced the patient to seek and to submit to surgical help. The parts were exposed by means of an incision in the left linea semilunaris and an oval body was exposed on the sigmoid flexure of the colon; its hardness led me to regard it as a malignant tumour. The adjacent walls of the gut were very thick and seemed so infiltrated with what I regarded as cancer that a wide colectomy was decided upon and the cut ends of the colon were secured separately in the abdominal incision. The resected portion after the usual preparation was bisected and in the middle of the suspected cancerous lump I found a smooth, round, pill-like body lodged in a smooth-walled cavity communicating with the mucous surface of the bowel by a narrow tubular channel. The globular body in the cavity had a fragment of straw for a nucleus (Fig. 4). The course of events in this case may be explained as follows. The piece of straw ingested with food perforated the wall of the colon in the immediate vicinity of an epiploic appendage and caused a small leakage of bowel contents. The extravasation of fæcal matter into the epiploic appendage infected it and set up inflammatory changes which transformed this fatty fringe into a large oval lump. The continued presence of the fæcal concretion which had formed around the piece of straw acted as an irritant and prevented the sinus from closing, and the inflammatory changes extended into the walls of the colon immediately adjacent. Some months later I resected the exposed ends of the colon and successfully restored the continuity of the bowel.

FIG. 3.



Diagrammatic [illegible] of a fæcal abscess in an epiploic [illegible] sigmoid flexure of the colon, [illegible] body escaping from the gut. (Case 1.)

FIG. 4.

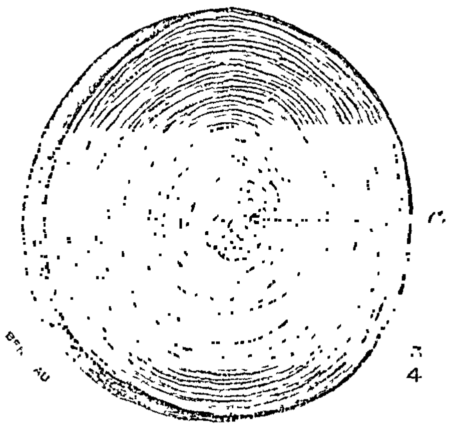


Diagrammatic view of a fæcal abscess in an epiploic appendage of the descending colon; it contained a pill-like body formed of inspissated fæces with a fragment of straw for a nucleus. (Case 2.)

In reflecting on these two cases it at once became obvious that other surgeons had probably encountered similar lesions and a suspicion arose in my mind that possibly some of the cases reported as successful instances of the excision (or resection) of supposed cancer of the colon without recurrence may have been examples of abscess of an epiploic appendix caused by a minute foreign body. A careful examination of the publications of those surgeons who have devoted much time and careful attention to the operative surgery of the intestine and of the colon in particular shows that they make no mention of foreign bodies in the appendices epiploicæ, and my inquiries in regard to this matter among physicians of great experience in maladies of the bowel being equally fruitless I ventured to think that the publication of the two clinical records which constitute the basis of this lecture may possibly focus attention on the subject and lead to the acquisition of some further knowledge. It may, perhaps, be useful to draw attention to some of the effects which follow perforation of the colon by small foreign bodies.

It is, I believe, true that a small piece of metal may traverse the wall of the gut and escape into the general peritoneal cavity and undergo encystment. Shattock[2] once found a rounded body with a diameter of 6·25 centimetres in the pelvis of a man between the rectum and the bladder. On section a piece of iron was detected in its centre (Fig. 5) surrounded by regular laminæ of structureless material. He regarded this as an instance in which a piece of metal taken into the alimentary canal had pierced the bowel and found its way into the peritoneal cavity and become encysted by exudation from the peritoneum. This explanation is satisfactory and the specimen is by no means unique. The peritoneum is frequently engaged in forming material such as is seen around this piece of metal. The conditions favourable for its production are sterile foreign bodies, coagulated fluids free from pathogenic micro-organisms, and especially cysts which are mobile, the spurious cysts which occasionally form around ovarian dermoids, the curious capsules around blood slowly effused from the Fallopian tube in the condition known as "tubal abortion" (Fig. 6), as well as those which surround sterile exudations from the tubes (Fig. 7), and the very complete fibrous capsules which invest echinococcus cysts projecting into the abdomen from the liver and more particularly those which grow in the omentum. This also explains how echinococcus colonies in the abdomen are provided with thick false capsules, whilst those which grow in the cerebrum have none. These observations prove also that the very large size of an epiploic appendage which contains a foreign body is in a large measure due to the deposit of lymph on its periphery and its subsequent organisation providing for it a stout and firm capsule. Speaking from my own observations, I think it quite exceptional for a piece of metal or other small body to penetrate harmlessly the wall of the intestine It is a matter of common knowledge that when an ingested foreign body, especially a sharp fish-bone which resists the action of the digestive juices, a needle, or some similar thing, has its easy ejection hindered by the sphincter, the wall of the bowel immediately adjacent is apt to be perforated and this leads to

FIG. 5.



The sectioned surface of a rounded body found between the bladder and the rectum of a man. The centre consists of a piece of iron (a) surrounded by laminæ of structureless material. The piece of metal probably perforated the bowel and escaped into the general peritoneal cavity and became encysted by peritoneal exudate. (Shattock's specimen, Museum, St. Thomas's Hospital.)

---

[2] Transactions of the Pathological Society, vol. xliv., p. 151.

the formation of an anal abscess. This painful and very common condition is fortunately easily and, as a rule, successfully treated by means free from risk to life. As a matter of fact the abscess in the epiploic appendage which we have been considering is pathologically of the same character as an anal abscess which has burst internally and left a sinus communicating with the bowel. I have satisfied myself from a careful study of a number of patients under my own observation and care that some puzzling cases of suspected abdominal tumours which spontaneously disappear and some which are treated by exploratory incisions and declared to be irremoveable cancers and then, in spite of the gloomiest prognostications the patient rapidly recovers and lives to mock at his advisers. In 1894 Greig Smith read a paper before the Royal Medical and Chirurgical Society on the (So-called) Spontaneous Disappearance of Solid Abdominal Tumours based on the observation of three cases;[3] the leading features of these cases were the presence of a solid tumour in the abdomen, the absence of pyrexia, clinical evidence of malignancy on abdominal section, and ultimate disappearance of the tumour with complete restoration to health. Having had some experience of these "disappearing tumours" I took part in the discussion which followed the reading of the paper and propose to reproduce briefly here the details of the most striking case (the remarks are fairly fully reported in the Proceedings of the Royal Medical and Chirurgical Society, Third Series, vol. vi., p. 46). A married woman, 56 years of age, had had for some weeks trouble with her bowels which culminated in signs indicating obstruction in the descending colon. Scybala could be easily felt in the colon and on vaginal examination a tumour could be made out feeling like an impacted fibroid. The patient after her ad[illegible] l by several c[illegible] eventually c[illegible] lump was exposed by an abdominal incision the uterus and the sigmoid flexure were found firmly adherent to each other and the thickening of the wall of the bowel and enlargement of the body of the uterus led me and those of my colleagues who attended the operation to regard the case as one of primary [illegible] adherent to, and [illegible] efore unsuited for [illegible] was sutured, the patient returned to bed, and [illegible] the relatives. Fortunately, [illegible] subsequent course of events [illegible] and left the hospital. Many weeks later, wishing to know what had happened, I called upon the patient and found her occupied with domestic duties and in excellent health. For many years she continued well.

FIG. 6.

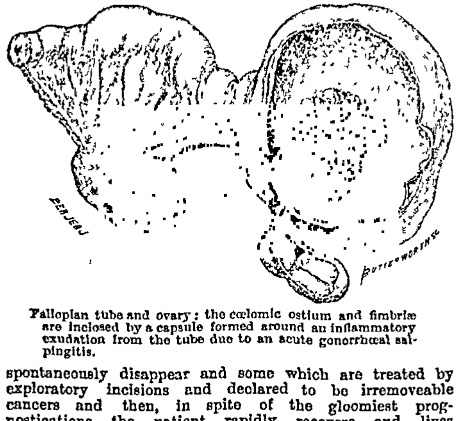
FIG. 7.



Fallopian tube and ovary; the cœlomic ostium and fimbriæ are inclosed by a capsule formed around an inflammatory exudation from the tube due to an acute gonorrhœal salpingitis.

I have subsequently had experience of similar cases and have learned to recognise them. In the light shed by the study of an abscess in an epiploic appendage I believe there can be little reasonable doubt that in some instances at least the cause of the tumours of the abdomen which disappear spontaneously after operation is a minute foreign body which has perforated the cæcum, the colon, the sigmoid flexure, or the rectum. It may perhaps be worth while to draw attention to the perfect way in which the piece of straw, which was the cause of trouble in Case 2, is completely surrounded and isolated by hardened fæcal matter, for it indicates very satisfactorily to my mind the way in which angular and dangerously pointed bodies may traverse the colon and be safely ejected without harm to the host—that is, they probably serve as a nucleus for the conglomeration of fæcal matter and, carefully isolated in this way, they escape through the anus without injuring the bowel wall in the neighbourhood of the sphincter, for common as anal abscess is I feel sure that it stands numerically in very small proportion to the great number of small foreign bodies which are daily ingested and egested. Be this as it may, it certainly supports the traditional and vulgar manner of treating patients known to have swallowed foreign bodies, especially pins, by making them eat very freely of suet dumplings.

Brook-street, W.

THE CORRECTION OF HEREDITARY TENDENCIES.

By SIR SAMUEL WILKS, BART., M.D. LOND., LL.D. EDIN., F.R.S.

I HAVE read with much interest the controversial letters on the laws of heredity which have appeared in THE LANCET and on these I will only make one comment—that I fear, on the one hand, that some of the writers seem to be influenced in their statements by their conviction of the absolute truth of the Darwinian doctrine of the non-transmission of acquired habits, whilst, on the other hand, there are some who make opposed statements as they hold the doctrine to be only partially true. There should be no suspicion of a bias in the scientific mind, for such an expression as "it must be" looks as if there was an endeavour to make the facts fit the creed.

---

[3] THE LANCET, Jan. 27th, 1894, p. 207.

I am not about to write on the question lately discussed, although certain phrases used by some of the writers have prompted the present communication.

My subject is the question of how far hereditary tendencies may be modified or arrested in the *individual*, as it is one the importance of which cannot be overrated. It is intimately connected with the education and the training of children, besides its being regarded as one of the functions of the medical man when his opinion is sought by parents as to the future of their sons and daughters. I myself believe firmly that very much may be done to arrest the development of many inherent traits and therefore I have never failed to contradict when possible any writer or preacher who asserts that the medical profession is teaching the immoral doctrine of irresponsibility and that criminals are only repeating the inherited vicious acts which their fathers had perpetrated before them. Although assenting to the dictum that we are all the victims of our organisation and knowing that the proofs of hereditary influences are too strong to be gainsaid, yet I equally maintain that these propensities may be arrested or so modified in childhood as almost to change the character. In judging therefore of a person's acts it is as important to ascertain his early surroundings as it is to discover his hereditary tendencies. I have therefore always denied that the medical profession holds unreasonably to the doctrines of irresponsibility and fatalism.

The facts of hereditary tendencies are too frequent and striking to be overlooked, as in the case where we see a whole family go wrong. For some criminal offenders we have often felt more pity than anger and especially when we have seen that they possessed no power of control over their inheritance. In a long experience I have seen too many cases of inherited vicious propensities to doubt the fact, but I am equally impressed with another fact—that these evil tendencies may be greatly corrected by appropriate counteracting surroundings. If these are not forthcoming and a child with evil propensities is forced to dwell in an atmosphere where such propensities are developed he soon goes to ruin; on the other hand, if he is removed to other surroundings a very different life may be expected. The value of education is this respect has probably been more accepted in England than in any other country; it does not mean cramming a boy with learning but treating him in a manner whereby the qualities of self-respect, integrity, independence, and a just dealing with others are brought out. Taine and some other French writers have explained that when they recommended the discipline of our public schools they had in view the importance of training the character. The Duke of Wellington properly appraised this when he declared that the battle of Waterloo was fought out at Eton, at Harrow, and at Rugby. The very common belief that a certain tone belongs to a school could have no meaning unless it were equally true that individual propensities were suppressed or modified. It might be said that when a Rugby boy was at one time always recognisable it was due to a mere mannerism or to the possessing a local "slang," but if this was true in part there remained the greater truth that he was the recipient of something much deeper which was perceptible throughout the whole of his life. It may be remembered that when Arnold had unwittingly received into his school an especially vicious boy he considered it a waste of time to bestow his energies upon him and wisely got rid of him. But lately the Rev. John Watson ("Ian Maclaren"), who thoroughly understands boys and school life, gave an address on the Education Act and in this he was reported to have said that the real educator and guardian of the youth was the schoolmaster. It was not the parent or the parson but the schoolmaster who made the boy; he might be tinctured by the Archbishop of Canterbury on the one hand or by the Kirk on the other but this did not much matter. The example and discipline of the school prevailed over all precepts. Such an opinion as to the capability of a boy's character being affected by education is of immense importance when coming from a man of such great perception and experience.

I have heard exactly the same sentiment expressed by intelligent schoolmistresses when they have declared that the influence of the school over froward children has been of greater value than any teaching at home. A little girl, for example, has bad habits of various kinds, but when placed with other children there is no opportunity for their display; they naturally disappear and she at the same time almost necessarily adopts some newer and better ones and consequently she exhibits no more peculiarities for fear of being pointed at by her comrades. A few weeks' discipline of this kind without any actual correction has sufficed to change the whole outward character of the child. It is often said that the weak side of the board school is that it tends to bring all the pupils to a dead level of uniformity and so suppresses individual genius. Whatever amount of truth there may be in this it is equally true that the school tends to suppress as well evil habits and propensities.

I have seen some very remarkable examples of the influence of new surroundings in children. I have frequently before my mind the case where the children in a family took more or less after their ill-tempered and wrong-headed mother, but on their being sent to a boarding-school, with the exception of one, and receiving a good education they were able to get on in life although with many vicissitudes. The remaining boy brought up at home had the very worst of educations possible and although of considerable ability he grew up utterly worthless. His own natural propensities were actually fostered. I am also well acquainted with another case of an opposite kind. Both parents were vicious in various ways and all the children except one, as might have been expected, went to the bad. The boy spoken of was adopted when young by some childless relatives who were highly cultured, refined, and in every way most worthy people, so that all his surroundings were as good as those of his brothers and sisters were bad. He filled the situation in which he was placed admirably and entered into all the good works in which his foster-parents were engaged. Everyone spoke of him as a most excellent lad. Whenever I talked to him I judged from his conversation and manner and allusions to newspaper stories that his mind wandered into other regions, and I felt a conviction that he was kept straight by the force of circumstances and that if by chance he had gone from his adopted home into a different atmosphere he would have lost his balance and wandered from the right path. In some cases, therefore, I have every reason to believe that the hereditary tendencies were changed by the new environments but in others they were only suppressed; still this does not diminish the value of new surroundings.

Medical men are constantly asked about the education of children, especially when these are froward and unruly; and when they see that fresh influences are required and the question of a boarding school is raised, the mother often protests, with the fear that her child may be contaminated in morals and that a mother's care must necessarily be the best. There is a show of reason in this, for a very vicious girl is capable of contaminating all her school-fellows, but, on the other hand, the mother seldom perceives the amount of harm done by her own way of bringing up, so that I feel confident that in a large majority of cases the boarding school is a much better place for the education and the formation of character than the home. It is unpleasant to tell the parent that she is the worst person to have charge of her child and yet this fact may be most apparent to others. I remember the case where a well-meaning but severely tyrannical woman felt it her duty to bring up her child in the habit of obedience and so compelled him to do certain things and to desist from others in which he might be innocently engaged. This brought about deceit and story-telling. When he grew up and was found to be both deceitful and an inveterate liar I attributed it to the mother's continued thwarting him on principle. If a mother possesses some fault or weakness it is probable that the child may also inherit it. In this case the mother often in the most natural manner encourages and develops it in her child. Sometimes this is most flagrant. In one case I have seen a very frivolous woman whose mind was wholly engaged on herself and her outward appearance dress up her little girl in the most fashionable finery, put a fan in her hand, and make her walk up and down before the admiring visitors whilst she went through all the manœuvres of a coquette. Or, again, a woman will dress up her little boy in the most extravagant costume and parade with him through fashionable streets as she would with her pet dog. All these and similar things are done for the mother's vanity, but woe to the child. Such cases might almost warrant the interference of the society for the protection of children. There are, unfortunately, a large number of cases less odious than these but equally mischievous where the parents bring the child into prominence on account of some remarkable gift which he or she is thought to possess and this, which is not unusually a very undesirable one, is developed by the devoted parents. A sharp, clever child who readily picks up anything he hears and will talk on any subject is trotted out before an admiring audience to recite or to make a speech, the parents being scarcely alive to the fact that a retiring, bashful, thoughtful child is generally the one of the greater mental power and of the greater promise. I have known several of these clever children who have at the same time no power of attention which is one of the very highest qualities that anyone can possess. This class of children should be sent to a boarding-school where all these clever tricks are suppressed. I mention these cases because, believing that hereditary tendencies may be suppressed or modified by education, it is the duty of the medical attendant of a family to make a serious study of the child on whose future he is asked to give an opinion, or even a final decision, as to the training and occupation.

In speaking of the influence of new environments on subjects which have inherited certain tendencies I might refer to the whole animal and vegetable kingdoms in proof of the contention. Wild animals are subdued not only by fear, as we see in the lion and tiger exhibitions, but by slowly taming as when a dog or a parrot is taught not to bite. In the vegetable kingdom this operation of new surroundings is most marked. A botanist was lately telling me of a plant which had been under his observation for many years and which in a neighbouring district had so altered in character that a modern book had described it under a different name either as a variety or a distinct species. I have been told also that the hereditary tendencies of many exotic plants are observed to alter when brought to this country and that material changes occur as they become acclimatised. The wondrous varieties which can be made in flowers by cultivation are known to everybody. When we speak of the times of the year in which trees and plants bud and flower, as well as the times for the pairing of birds and their migration, we are strikingly impressed by the fact of how much these may be altered by circumstances. Let there be, for example, exceptional weather in the early months of the year making them resemble those of spring the effect on all living things is marvellous—the whole aspect of nature has undergone a change and is bursting into life, the trees begin to bud and the smaller plants to flower and the thickets become green. In the animal kingdom it is the same—the birds come forth and pair, they begin to build their nests, and their songs are heard all around.

I may mention one particular instance of the influence of sun and air by an example always before me. When I came to my present residence two years ago there grew a handsome plane tree close to the back of my house; as it shut off the light and warmth from the rooms I determined to sacrifice it. When it was cut down I had a slice taken from the trunk a few feet from the ground. On examination of the section the usual centre or pith was quite away from the true centre, being placed towards one side, and then on counting the annual rings I found in a corresponding manner that they were much narrower on the smaller side than on the other. This narrow side represented the part of the tree next the house, the broader, expanded part was that which looked out into the garden and received the warmth of the sun and more air. This specimen, which is before me on my desk, is always preaching to me the lesson which I have been inculcating—the importance of surrounding influences; that all living things are dependent for their character on two things—their hereditary tendencies and their actual surroundings. In the human being the latter may be called education. My particular object in writing this paper is to enforce the power of environment on the hereditary tendency. I will go no further than to say that I speak only of the individual, whether the alteration may be continued in the progeny I will leave to others to decide.

Hampstead.

The Semi-Teetotal Pledge Association.—The committee of this association, of which Lord Roberts is President, is daily receiving fresh signatures to a definite pledge to abstain from all intoxicating drinks except at the midday and evening meals and 35,000 forms of pledge have been applied for. A branch has been formed in Cape Town and funds for extending the work are urgently needed. The honorary secretary is Mr. G. H. F. Nye, 76, Regent-street, London, W.

ON THE USE OF PURE CARBOLIC ACID IN THE TREATMENT OF SMALL-POX.

By A. E. BRINDLEY, M.D. Lond., B Sc, D.P.H. Vict.,
MEDICAL OFFICER OF HEALTH AND MEDICAL SUPERINTENDENT OF THE FLORENCE NIGHTINGALE HOSPITAL, BURY;

AND

F. W. BONIS, B.A., M.D. Dub., D P.H. Birm.,
ASSISTANT MEDICAL OFFICER OF HEALTH, BURY.

In The Lancet of Feb. 21st, 1903, p. 518, there appeared an article by Dr. J. T. Neech, medical officer of health of Halifax, suggesting the use of pure carbolic acid as a local application in small-pox. He described two cases in which he had used this treatment with very beneficial results. As we have had a large number of cases of small-pox in the borough of Bury during the past nine months there has been ample opportunity for testing the value of this method and we think it advisable to record briefly the results of our experience of this remedy. In order the better to form an opinion as to the efficacy of carbolic acid when used in its undiluted form to modify the course and termination of small-pox, we selected for treatment for the most part severe cases occurring in unvaccinated subjects. As the anti-vaccination element is very prominent in Bury and also in some of the neighbouring districts we have had, perhaps, an unusually large proportion of unprotected cases to deal with, hence the results of this particular line of treatment are not so liable to be complicated by the modifying effects of vaccination.

The treatment is carried out in the following manner. The pure acid in a liquefied state is applied to the vesicles over a limited area with a small camel's-hair brush, the application being made on successive days. On the first day the face and neck are selected for treatment, on the following day the hands and the arms, then the lower extremities, and, finally, the trunk. The effect of the acid is seen in the rapid shrivelling up and scabbing of the vesicles. A second or third application may be made if necessary over certain parts of the body. An important detail of the treatment is to secure the early removal of the scabs, either by an oil poultice or otherwise, as this tends to prevent subsequent abscess formation.

This method of treatment is, of course, one which takes some time to carry out, as it must be done carefully and thoroughly if the best results are to be obtained. There is no reason why it should not be intrusted to an intelligent nurse with instructions to use the acid cautiously in the neighbourhood of the eyes and not to allow it to run on the healthy skin. The treatment is found to cause little or no pain or discomfort; in fact, it relieves the intense irritation which is so prominent a feature in small-pox. We have not observed any signs of carboluria or other evidence of toxic action from absorption of the drug. The effect would appear to be purely a local one, the acid penetrating the walls of the vesicles and pustules, disinfecting their contents, and hence preventing the absorption of septic matter into the system. The accompanying table gives particulars of some of our cases.

As will be seen from a reference to the table, one of the most striking results of the treatment is the comparative mildness of the secondary symptoms or those coincident with the maturation of the pustules. In many of our cases the patients expressed themselves as feeling well and hungry by the eighth or ninth day after the appearance of the rash or even earlier. By this time the pustules on the face will have disappeared and the great majority of those on the limbs and trunk will have dried up or aborted. After the temperature has fallen on the appearance of the eruption it usually remains at a low level during the rest of the illness, even in severe confluent cases averaging not more than 100° or 101° F. In several of our patients the temperature was practically normal throughout. A corresponding improvement is noticed in the state of the pulse and the general symptoms.

With regard to the subsequent pitting we are of opinion that the carbolic treatment is decidedly beneficial in lessening disfigurement, although it is not to be relied on as a certain preventive. We think it reasonable to conclude that, by shortening or modifying the severity of the pustular stage of the disease, the liability to the formation of deep and permanent scars is diminished. Another point is that this use of the germicide tends to diminish the risk of infection from aerial convection and to remove the disagreeable odour which accompanies many cases of the disease.

The total number of cases treated by us up to the present has been 35, of which 22 were of a severe kind, mostly confluent, more than half of these being in unvaccinated subjects. Five of the cases proved fatal, two of which were children suffering from scarlet fever, while the third was one of malignant small pox with minute subcutaneous hæmorrhages and death during the papular stage. We may say that in the earlier part of the epidemic we confined ourselves to using the acid on the face and hands with the idea of diminishing the scarring, but in order to obtain the best results it is necessary to apply it carefully over the whole body as described.

Table giving Particulars of the Use of Carbolic Acid in Small pox.

No. of case.	Sex.	Age (years).	Vaccination.	Type of disease.
1	M.	14	Unvaccinated.	Severe confluent.
2	M.	56	,,	,,
3	M.	8	,,	,,
4	F.	42	In infancy.	,,
5	M.	32	,,	Confluent.
6	M.	10	Unvaccinated.	,,
7	F.	35	In infancy.	,,
8	M.	8	Unvaccinated.	Severe confluent.
9	M.	31	In infancy.	,,
10	M.	14	Unvaccinated.	,,
11	M.	39	,,	Confluent.
12	F.	40	,,	Severe confluent.
13	M.	35	,,	,,
14	F.	6	,,	Hæmorrhagic.
15	F.	46	In infancy.	Severe confluent.
16	M.	28	,,	Discrete, rather severe.
17	M.	30	,,	Discrete, fairly severe.
18	F.	10	Unvaccinated.	Confluent.
19	M.	34	In infancy.	Discrete, fairly severe.
20	F.	12	Unvaccinated.	Discrete, severe.
21	M.	46	In infancy.	Malignant confluent.
22	M.	6½	Unvaccinated.	Severe confluent.

REMARKS.

CASE 1.—Some secondary fever was present; recovery. There was no pitting. The acid was applied to the face and the arms only.

CASE 2.—The patient was an alcoholic and in a low state of health. Severe pulmonary symptoms developed. The temperature remained high throughout. Death occurred on the tenth day of the eruption.

CASE 3.—The patient was suffering from scarlet fever when attacked by small-pox; there were severe initial symptoms. Death occurred on the fourteenth day of the eruption.

CASE 4.—The temperature fell to the normal on the fifth day after the eruption; recovery ensued.

CASE 5.—No [illegible] fever was present; recovery ensued. The [illegible]

[illegible] ittle or no secondary symptoms. The convalescence was slow owing to an abscess on the face.

CASE 7.—The febrile symptoms were slight. Recovery ensued.

CASE 8.—Secondary symptoms were almost absent. The patient was quite convalescent by the ninth or tenth day.

CASE 9.—The face only was treated with the acid. The case was prolonged. Slight scarring resulted.

CASE 10.—The acid was applied to the face and *arms only.* The case was somewhat prolonged, being complicated with boils. There was very slight scarring on recovery.

CASE 11.—The recovery was rapid, with practically no pitting.

CASE 12.—There was no secondary fever. A rapid convalescence was followed by very little disfigurement.

CASE 13.—The patient had a bad alcoholic history. Severe delirium and insomnia were present for three days, requiring large doses of morphia. The temperature during the secondary stage only once reached 101° F. The recovery was rapid.

CASE 14.—This case was a very malignant one. There were numerous minute subcutaneous hæmorrhages and marked pulmonary symptoms. Death occurred on the third day of the eruption.

CASE 15.—There was a rapid convalescence after the eighth day of the eruption.

CASE 16.—The temperature became normal on the fifth day of the eruption. The convalescence was rapid.

CASE 17.—There was no fever after the initial stage. The patient made a good recovery with very slight scarring.

CASE 18.—There was slight fever; recovery ensued.

CASE 19.—No fever was present; recovery ensued.

CASE 20.—There was no secondary fever; recovery ensued.

CASE 21.—The carbolic treatment was only used on the face and the wrists. The patient died.

CASE 22.—The patient was suffering from scarlet fever with an abscess of the neck. Death ensued. The acid was applied to the face and the wrists only.

Bury.

THREE CASES OF ERYTHEMA EXSUDATIVUM MULTIFORME.

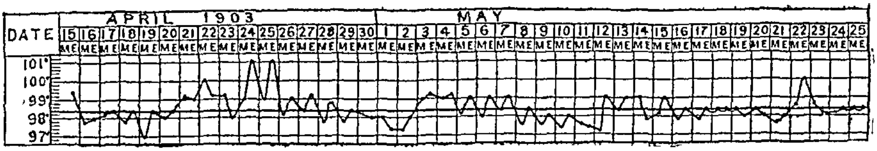
BY RAYMOND CRAWFURD, M.A., M.D. OXON., F.R.C.P. LOND.,
SENIOR ASSISTANT PHYSICIAN, KING'S COLLEGE HOSPITAL; PHYSICIAN TO THE ROYAL FREE HOSPITAL.

IT has seemed to me worth while to record these three cases and in some detail, not so much because of the comparative infrequency of the disorder as that they throw some light on a condition that has been rendered obscure largely on account of a faulty nomenclature. The three cases in virtue of the gastro-intestinal crises that were marked in all would be commonly termed Henoch's purpura but seeing that the particular syndrome of symptoms depicted by Henoch is merely one manifestation of a morbid state that exhibits protean changes of form the attempt to establish them as a distinct clinical entity can only serve to make more difficult the search for the underlying cause. The name that I have preferred to use is adopted from Osler as the best to hand, in that it enables us to group all the variations of type under a single head. In these cases of mine purpura and erythema were alone seen but Osler has also described urticaria and other conditions. In the most constant symptoms of the disease—that is to say, in the skin lesions, in the articular and peri-articular effusions, and in the abdominal crises—we are apparently dealing with a number of extravasations either of blood or of serum, but in the presence of nephritis and endocarditis, each of which was present in one or other of my cases, we are driven a step further back. In the light of other diseases we can hardly doubt that we have to do with a toxæmia which, like that of scarlet fever, spends itself with varying force on the skin, the kidneys, the heart, and the joints, and which in its cutaneous features presents a marked symmetry. In all of these three cases I have had careful cultures made of the blood but in each instance with negative results. I have not hesitated to refer the crises of abdominal pain to extravasation because of the close association of this symptom with extravasations that are visible to the eye on the surface of the skin. Moreover, one has in mind the visceral hæmorrhages—suprarenal for example—that are so commonly found in cases of purpura fulminans. The abdominal symptoms are such as may well be due to effusion into the wall of the gut and in one case that I have seen, but which is not here recorded, the diagnosis of acute intestinal obstruction was actually made until the appearance of the familiar symptoms cleared the picture. As to how far the nephritis affects the immediate and remote prognosis it is, of course, impossible to infer from three cases; but in these and other cases that I have seen I have noted three different endings: in one case the patient died in some three days from the most intensely acute nephritis imaginable, in two others, of which Case 1 is an example, all signs of kidney disease subsided, and in another, to wit in Case 3, it seemed that the originally acute nephritis had settled down into a chronic condition.

CASE 1.—The patient was a lad, aged 16 years. He was admitted into King's College Hospital on August 15th, 1902, complaining of a rash and pain in the stomach on and off since the previous Christmas. The following notes were sent to me by Dr. R. P. Williams of Slough: "In January treated for purpura, followed by abdominal pain and vomiting; next the ankles and knees swelled and the temperature rose to 101°F. Hæmorrhage from the gums and kidneys followed, after which he recovered, having been ill six weeks. After this he was kept under observation and treated with perchloride of iron and sulphate of magnesia. In March, 1902, a further eruption of purpura. In July, 1902, the present attack commenced with diffuse swelling of the left wrist (involving both tendon sheaths and joint), abdominal pain appeared as before, the vomiting was less than on the previous occasion, and blood casts were found in the urine." The family history and personal antecedents of the patient were quite unexceptionable. He had a comfortable home and was well fed. The temperature on admission was 100°. The pulse was quick and markedly bigeminal. There was a faint blowing systolic murmur at the apex. The lungs were normal; there was no hæmoptysis. The urine was acid and of specific gravity 1037; it contained much albumin, was muddy, and urates were present in abundance; there were no casts and no blood. The skin as a whole was moist. On both arms and legs, front and back, there were numerous colonies of red "freckles" which did not disappear on pressure. On August 17th a fresh crop of spots had appeared in the last 24 hours on the outer side of the right upper arm. These ranged in size from that of a pin's head to that of a lentil; they were painless, reddish purple, and did not fade on pressure. He had vomited in the morning. His temperature had fallen to 99°. He was kept on a milk and soup diet. On the 18th the spots were fading but he had vomited again during the night. The temperature was normal. On the 22nd there was a general subsidence of all the symptoms. On the 24th during the night a fresh crop of purpuric spots, closely massed together, had appeared symmetrically around each ankle and on the dorsum of the feet, a few also on the extensor aspect of each upper arm. There was also some nagging pain in the umbilical region. There were no joint pains. The temperature was normal. He had a general sense of fatigue and this was always the case when a fresh crop of spots appeared. On the 25th the blood examination was as follows: red cells, 5,825,000 per cubic millimetre; white cells, 13,743 per cubic millimetre; hæmoglobin, 77 per cent.; polymorphonuclears, 66·6 per cent.; lymphocytes, 25 per cent.; eosinophiles, 5·8 per cent.; uninuclears, 2·2 per cent.; and basophiles, 0·4 per cent. The blood was sterile. On the 29th the pulse tension was very low. Adrenalin hydrochloride was given thrice daily by the mouth. On Sept. 1st the blood examination gave the following results: red cells, 5,000,000 per cubic millimetre; white cells, 6500 per cubic millimetre; hæmoglobin, 80 per cent.; polymorphonuclears, 59·7 per cent.; lymphocytes, 29·3 per cent.; uninuclears, 4 per cent.; and eosinophiles, 7 per cent. On the 2nd there had been no revival of symptoms since August 24th. The rash had disappeared. The amount of albumin in the urine was very small. The adrenalin showed no measured effect on the blood pressure. The patient had light diet with fish and was allowed to get out of bed into a chair. On the 3rd a fresh crop of purpuric spots appeared on the back of both feet as far as the heads of the metatarsals; there were no other symptoms. On the 5th the eyes were examined. The retinal veins were engorged; pulsation was to be seen in the left inferior vein at its entrance to the disc. There were a few scattered pin-point hæmorrhages over the fundus most marked in the periphery of the left eye. They resembled those on the feet but were smaller. By the 9th there had been steady improvement. The systolic murmur at the apex was constant. On the 10th the blood was sterile. On the 17th the patient left the hospital, having lost all his symptoms but still with the apical bruit. There was no albumin in the urine.

To summarise this case there were—(1) symmetrical outbreaks of purpura; (2) articular and peri-articular effusions—sometimes symmetrical and sometimes not; (3) attacks of abdominal pain usually associated with the other symptoms; (4) hæmorrhage from the gums and the kidneys; and (5) casual disturbance of temperature; but the notable feature of the case is that in successive attacks not all the symptoms were present. In fact, if we were to adopt the current nomenclature we should have to say that this patient had simple purpura, Henoch's purpura, and arthritic purpura successively, though it is obvious that he had but one disease variously manifested. A tendency to recurrence is seen in this patient's illness.

CASE 2.—The patient was a boy, aged 14 years. He was admitted into the Royal Free Hospital on April 15th, 1903, complaining of a rash and pains in his elbows and knees. For nearly three weeks he had been ailing and for four days he had been conscious of stiffness and discomfort in these joints; he took to his bed three days before admission to hospital and almost immediately a red rash appeared on his legs and thighs. The knees and elbows became so painful that he was obliged to go to the hospital. While waiting in the casualty department he vomited and complained of pain in his back. In his previous history there was nothing noteworthy beyond the fact that he had lately been short of food. There was no history of epistaxis or other hæmorrhagic tendency. The family history was unexceptionable but for the fact that the father was very subject to epistaxis and once had an attack lasting for three days and a younger brother had a tendency to bleed at the nose on the slightest provocation. On admission the temperature was 99·4° F., the pulse was 72, and the respirations were 28. On the feet, the legs, the thighs, and the buttocks there was a bright red petechial rash of markedly symmetrical distribution. The spots varied from scattered specks to irregular clumps; they were not raised and did not disappear on pressure; those that had faded left brown stains. The most affected areas were the buttocks and the outer side of the legs and the thighs. Over the lumbar region and in several places on the legs there was a bruised appearance and the skin quickly reddened over any point of pressure. The skin as a whole was rather moist. The right elbow was swollen and discoloured and was kept flexed to a right angle; it was painful and more so on movement; it was tender to pressure and so was the adjacent portion of the humerus. The swelling of the left elbow had gone and also the pain on movement, but a bruised area remained which was slightly tender on pressure. The right shoulder was tender to touch and painful on movement but was not swollen. The left wrist was swollen and hot and very painful and tender. Both knees were hot, flushed, swollen, and painful, particularly the left; these were held slightly flexed; the swelling was irregular and had not the outline of the synovial membrane. There was a hot and tender swelling over the anterior part of the crest of the right ilium extending down into the iliac fossa, also over the right great trochanter and the posterior part of the left iliac crest. On the front of the chest on the right side corresponding to the second, third, and fourth ribs was an extremely painful swelling, seemingly in connexion with the periosteum. The lungs were normal and there had been no hæmoptysis. The heart was normal but for a reduplicated second sound in the pulmonary area; the pulse was regular but of low tension. The tongue was clean, the gums were normal, and the teeth were good. There was loss of appetite and the bowels were constipated. The urine was of specific gravity 1025 and it contained no albumin, blood, or sugar. The spleen was not apparently enlarged but the splenic region was tender on pressure. The abdomen was rigid. On April 18th an examination of the blood showed: hæmoglobin, 68 per cent.; red cells, 3,250,000 per cubic millimetre; white cells, 60,000 per cubic millimetre; polymorphonuclears, 81 per cent.; large lymphocytes, 6 per cent.; small lymphocytes, 11 per cent.; and eosinophiles, 2 per cent. The blood was sterile. The right elbow was in the same state as on admission. The swelling and pain of the left wrist had extended to the back of the hand. The condition of the knees was unchanged. The swelling on the front of the chest had almost subsided but that over the right iliac crest and in the right iliac fossa was larger and very tender. The rash as a whole was disappearing but there were several fresh ecchymoses about the ankles. The pain had prevented him from sleeping. On the 20th, on a simple milk and soup



Showing range of temperature in Case 2.

diet, the patient had improved greatly. His elbows and knees had quite recovered. The left shoulder was swollen, particularly behind, and was very painful. There was a further petechial eruption on the left arm and about the left ankle. Salicylate of sodium was ordered in ten grain doses thrice daily. On the 21st both shoulders were swollen and very painful and there was a bluish effusion in each axilla—obviously blood. The other affected joints were all better. There was a good deal of lumbar pain but no swelling. On the 22nd the morning temperature was 100°. The rash on the left arm was more abundant and it had also appeared on the right elbow. There was a very painful swelling over the right costal margin and the knees were discoloured. In spite of this the patient felt better and took food fairly. On the 23rd the temperature had fallen but there were a fresh crop of the eruption on both knees and a painful swelling just below, the insertion of the right deltoid and a similar one on the right thigh. Iron and arsenic were substituted for the salicylate and the diet was increased by cocoa and lightly boiled eggs and custard. On the 24th a painful swelling had appeared in the right temporal region and that of the costal margin was larger and more painful. On the 25th the temperature had risen to 101° during the night. The right upper eyelid was swollen and blue; the penis was much swollen and so was the prepuce. There was also effusion into, the scrotum. Micturition was painless and the urine was normal. There was a painful swelling in the right side of the abdomen, apparently in the abdominal wall. Calcium chloride in five grain doses was given thrice daily instead of the iron and arsenic. On the 27th the patient had very severe pain in the abdomen; he lay with his knees drawn up and could not bear his abdomen to be touched; seven grains of phenacetin were given at once. The bowels had been opened freely on the previous day. The left eyelid was swollen and bluish. Milk and soup diet was again given. On the 28th both knees were again swollen and painful and kept semi-flexed; the abdominal pain was much better; the swelling of the eyelids and penis had disappeared. The dose of calcium chloride was increased to seven grains. On the 29th the right wrist and lower end of the ulna were swollen and painful; there was a copious eruption on both forearms and feet and on the outer side of both legs. On the 30th there was again great abdominal pain. On May 2nd there was a general improvement; there was freedom from pain and the rash and swellings were all disappearing Blood examination showed: red corpuscles, 4,250,000 per cubic millimetre; white corpuscles, 37,000 per cubic millimetre; and hæmoglobin, 68 per cent. On the 4th he had an attack of acute abdominal pain. Three minims of morphia were injected. On the 10th there was a symmetrical eruption on the extensor surfaces of both forearms and arms, also on both buttocks and over the lumbar spine, where there was also pain. On the 14th, after the temporary relapse, there was again general improvement. On the 19th calcium chloride was replaced by nux vomica, sal volatile, bicarbonate of sodium, and chloroform water thrice daily before meals. A differential count showed: polymorphonuclears, 67 per cent.; lymphocytes, 31 per cent.; and eosinophiles, 1 per cent From the 20th to June 5th the patient mended rapidly and was sent to Broadstairs on the latter date.

To summarise this case there were: 1. Eruptions of purpura, symmetrically placed. 2. Hæmorrhagic effusions: (*a*) about the joints, (*b*) in connexion with bones and seemingly subperiosteal, and (*c*) in the lax subcutaneous tissues. These effusions showed a tendency to be symmetrical. 3 Attacks of abdominal pain, usually contemporaneous either with the hæmorrhagic effusions or with the outcrops of purpura and therefore probably referable to like causes—i.e., extravasation. 4. Slight disturbance of temperature. This did not appear to be an integral part of the disease but rather a casual complication, depending on such causes as pain, sleeplessness, and so on. The changes in the blood were neither constant nor characteristic, but the red cells and hæmoglobin were relatively low and the white cells relatively high. No drug that was employed had any obvious effect on the course of the disease.

CASE 3 —The patient was a Jewish boy, aged 10 years. He was admitted to King's College Hospital on August 30th, 1902, complaining of red urine and abdominal pain. He had been in Guy's Hospital under the care of Sir Cooper Perry from Dec. 4th, 1901, to Feb. 1st, 1902, and the following notes were kindly supplied by the medical registrar. "He gave no previous history of purpura. He had lived most of his life in Russia. His symptoms appeared three weeks after his being vaccinated and he was admitted for hæmoptysis, abdominal pain, and a purpuric rash all over his body and limbs but particularly over the buttocks, arms, and legs. There were purpuric spots even on the soles of his feet. The chest and abdomen, head and neck were almost free. He had also hæmatemesis and hæmaturia and passed bright red blood per rectum. He was very ill for a time but improved. He had pains in his elbow-joints at one time and these joints got stiff, apparently from hæmorrhage into them, but they entirely recovered. The hæmorrhage from the rectum was the most troublesome to cure; but ultimately all purpura and hæmorrhage cleared up entirely. The diagnosis was Henoch's purpura. The blood examination in December, 1901, showed red corpuscles, 3,866,660 per cubic millimetre; white corpuscles, 11,500 per cubic millimetre; and hæmoglobin, 80 per cent. He was treated at first with calcium chloride, ten grains every six hours; later by sodium salicylate and compound powder of kino, ten grains; and ultimately with compound syrup of phosphate of iron in one drachm doses." Since his discharge from Guy's Hospital in February he, had passed blood in the motions about four times and his urine was red-coloured about once a fortnight. He last noticed this on August 20th; it was followed by abdominal pain lasting about 12 hours, and he passed blood in his motions; occasionally he had pain during micturition. On admission the boy was very thin and bloodless. His temperature was 100° F. His heart, lungs, liver, and spleen were normal. The urine was of specific gravity 1012 with some blood, a large amount of albumin, some granular tube casts, and some red corpuscles. There were no eruption on the skin and no abdominal or joint pains. On Sept. 1st, after admission, he was given a dose of Epsom salts and passed one ascaris lumbricoides. On the 2nd no more worms were passed after santonin. A differential blood count showed: polymorphonuclears, 53·2 per cent.; lymphocytes, 43·2 per cent.; large uninuclears, 1·2 per cent.; and eosinophiles, 2·4 per cent. The blood was sterile. Adrenalin chloride was given in small doses thrice daily. On the 5th the patient was much improved and said that he felt quite well. With regard to the eyes, the veins were full and there was œdema of the retina along their course; there were no hæmorrhages. On the 8th there were purpuric spots on both buttocks and on the right knee and foot. On the 9th there was hæmorrhage of about half an ounce at a time in three motions. On the 10th calcium chloride was given in ten-grain doses every six hours. In the evening one ounce of blood passed from the bowel. On the 13th there was only a trace of albumin in the urine. On the 14th a group of spots appeared on the extensor aspects of the forearms. On the 15th the temperature was showing an irregular upward tendency. On the 16th there were petechiæ on the calf of the right leg; otherwise the patient was quite well. There was a trace of blood in the urine as well as the albumin; these were still present when the patient ultimately left the hospital on Oct. 7th.

To summarise this case there were: (1) symmetrical outbreaks of purpura; (2) symmetrical effusions into joints; (3) attacks of abdominal pain associated with the other symptoms; (4) hæmorrhage from the lungs, kidneys, stomach, and bowels; and (5) an irregular febrile temperature not waxing and waning with the other symptoms. A tendency to relapse rather than to recurrence is shown in the course of this case.

Harley-street, W.

A SIMPLE METHOD OF PERFORMING INTESTINAL UNION.

BY ALEXANDER MACLENNAN, M.B., C.M. GLASG., L M. DUB.,
VISITING SURGEON TO THE TRAINING HOME FOR NURSES; EXTRA HONORARY SURGEON TO THE ROYAL HOSPITAL FOR SICK CHILDREN; EXTRA DISPENSARY SURGEON TO THE WESTERN INFIRMARY, GLASGOW, ETC.

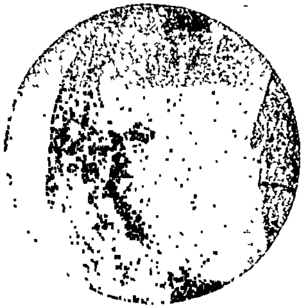
IN 1899 I suggested two methods for uniting divided intestine. The paper appeared in THE LANCET of Feb 25th of that year (p. 501)[1] and was a record of experimental work carried out in Berlin. Since then I have performed experiments upon dogs with the object of ascertaining whether formalin-hardened gelatin bobbins could be used as efficient substitutes for those made with decalcified bone. (It may be stated in passing that they proved most efficient.) During these experiments the method to be described was devised as an improvement upon the first method and I venture to hope that this modification will supersede the older and make the principle of wider application.

---

[1] The methods were described in (1) Illustrirte Rundschau der Medicinisch-Chirurgischen Technik, Jahrgang II., 2 Quartalheft; and (2) American Yearbook of Medicine and Surgery, Gould, 1900, p. 76.

The reproductions of two photomicrographs are shown to illustrate the effect on the intestine of this method as compared with the Czerny-Lembert method (see Figs. 1 and 2).

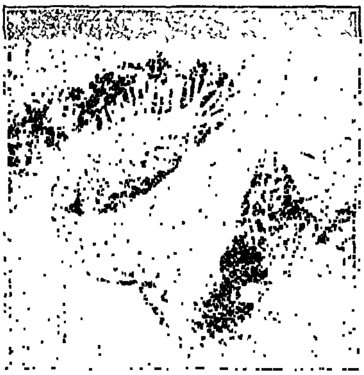
FIG. 1.



Condition of the bowel (in a dog) after the "bone-bobbin" operation.

The latter (Fig. 2) shows in a marked degree the annular shelving stricture so commonly found after this operation. The other shows how little interference with the finer anatomy has been produced by the "bobbin-and-ring" method about to be described.

FIG. 2.



Condition of the bowel after the Czerny-Lembert operation (also in a dog).

1. The bone bobbins (see Fig. 3) are made in four sizes so that when placed in a series, as it were to form a tube, the one end has a diameter of an inch and the other one of eleven-sixteenths of an inch. The bobbins are therefore slightly conical. The sizes are not hard [illegible] can [illegible] bbin [illegible] de a little more heavily (to permit of a deeper groove) so that the lumen of the little tube is even more conical than the outside conformation. Two objects are thus gained, firstly, the rubber ring slips more easily along the bobbin from the wider to the thinner end, and, secondly, when intestinal contents have once entered the narrower opening (the upper) there is less chance of the lumen becoming blocked, for the passage becomes progressively wider. There are three grooves in the bobbin: two at the distal end which are shallow and one at the proximal end which is deep. Beginning at the wide end the grooves may be, for convenience in description, designated *a*, *b*, and *c*. I have explained this bobbin somewhat in detail so that from the description the bobbin may be made by the bone-turner, as I have found that there was great difficulty in getting the bobbins all made alike. Some had the grooves too narrow, some too shallow, while in other cases the heaviness of the bobbin was greater at the wider end than at the narrow. These little points are of importance, for the smooth working of the method depends upon the nicety of the mechanism. The edges are rounded. The bone is decalcified completely or partially according to opinion.

FIG 3.

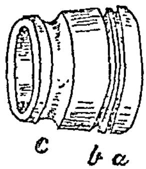


FIG. 4.

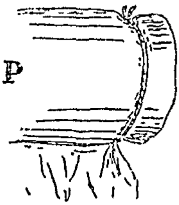
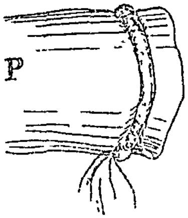


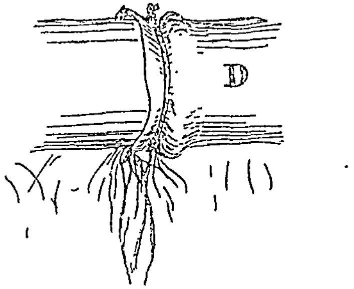
2. The bobbin is then to be inserted into the proximal end of the divided gut. (It is to be noted here that this is an important point, for should the bobbin be mistakenly placed in the distal end the whole mechanism is upset and the bobbin will become displaced laterally and so come to act as an obstructing foreign body.) The bobbin is fixed in the intestine by a ligature which binds the intestine into groove *a* (see Fig. 4).

FIG. 5.



3. Over this ligature is placed a rubber ring similar to an umbrella ring. For the larger sizes of bobbins a light umbrella ring will be suitable; for the smaller sizes lighter rings are necessary. The ring should be tight but not so tight as to prevent it being easily placed in position (see Fig. 5).

FIG. 6.

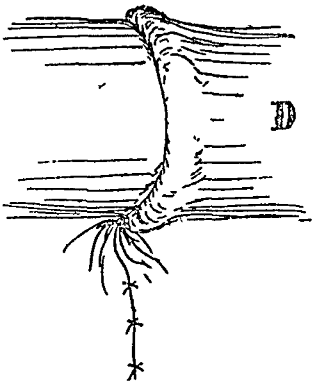


4. The proximal end of the intestine, so armed, is then

inserted into the distal end of the gut far enough for the gut to cover the groove *b*. The distal intestine is ligatured into this groove over the proximal end in a manner similar to that by which the proximal end is fixed to the bobbin. The ligature must be tight (see Fig. 6).

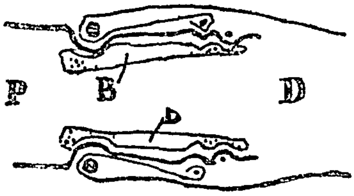
5. The rubber ring under the distal gut has then to be gently manipulated from its resting place over the first ligature in groove *a* into, and past, groove *b*. The conical shape of the bobbin favours this manœuvre and the ring glides very readily into groove *c*. Care must then be taken that the ring is not pushed beyond this groove (see Fig. 7).

FIG. 7.



The union is now completed by stitching the cut borders of the mesentery. From Fig. 8 it will be seen how the structures finally rest. Eventually all distal to the rubber ring comes away. The operation is an exceptionally easy one to perform and takes much less time to carry out than to describe. Sutures may be put in at the junction of the peritoneal surfaces but are not to be recommended as they lead to adhesions.

FIG. 8.



Note.—In the above figures P = the proximal end of the gut and D = the distal end. In Fig. 8 B is the bobbin shown in section.

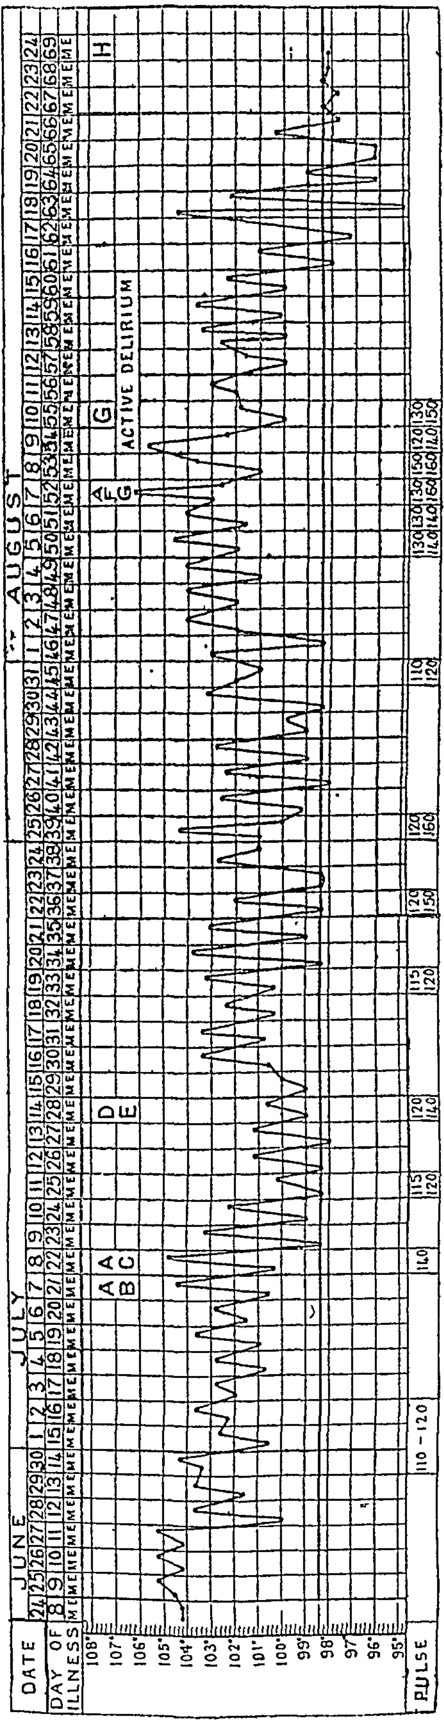
Glasgow.

ON THE VALUE OF SALINE INFUSION IN THE TREATMENT OF ENTERIC FEVER.

BY D. G. MARSHALL, M.B., C.M. EDIN.,
MAJOR, INDIAN MEDICAL SERVICE.

THE case here recorded shows the benefit to be derived from saline infusion, not only after hæmorrhage but in severe cases of enteric fever when during the third week of the disease the patient is in danger of dying from heart failure.

The patient, a married woman, aged 25 years, who eight weeks before had been delivered of her first child, complained of malaise from June 18th. On June 24th, when first seen, the temperature was found to be 104° F., the skin was dry, severe frontal headache was present, and the bowels were constipated. Careful examination of the blood for the malarial plasmodium gave a negative result. The patient's condition grew rapidly worse during the following days and the symptoms were so typical of enteric fever that an examination of the blood for Widal's reaction was considered unnecessary. The accompanying chart shows the progress of the case. The temperature in the early stage was kept in check by cold packing and later by sponging and the use of an ice-cradle. The early constipation was succeeded by diarrhœa which was not, however, very excessive.



A, Rigor. B, Injection of 20 ounces of saline fluid. C, Injection of 25 ounces of saline fluid. D, Severe hæmorrhage. F, Injection of 25 ounces of saline fluid at noon and also at 11 P.M. F, Injection of 30 ounces of saline fluid. G, Bloody stools. H, After this date the temperature remained normal till Sept. 1st when it began to rise and on Sept. 4th was 105° F.; it then declined gradually and became normal about Sept. 12th, after which the patient's recovery was uninterrupted.

On July 7th the patient's condition was serious, there was a severe rigor, the temperature was 105°, the heart sounds were very weak, and the pulse was almost imperceptible at the wrist. After a consultation it was decided that as the patient was evidently sinking from heart failure and there was no response to any of the ordinary cardiac stimulants the injection of saline fluid might be tried. 20 ounces were injected into the areolar tissue round the right breast at 11 P.M.; this was followed by some improvement in the pulse and the patient passed a fairly restful night. On the 8th she had a rigor, the temperature was 105°, and the pulse was very feeble. 25 ounces of fluid were injected. From the 9th to the 14th the condition improved, but on the latter date there was profuse hæmorrhage from the bowel, followed by profound collapse, with a pulse of 140. 25 ounces of fluid were injected at noon and at 11 P.M. There was some improvement up to July 29th, the temperature daily approaching the normal. On the 30th a relapse set in and on August 9th I was hurriedly summoned and found the patient suffering from a severe rigor. The temperature was 106·2° and the pulse was 160, intermittent, and could be counted with difficulty at the wrist; 30 ounces of fluid were injected. During the 9th and 10th the stools were tinged with blood. For a week after this the condition was critical. The patient was delirious, with a soft dicrotic pulse ranging from 130 to 160. On the 17th, at 2 A.M., the temperature was 104 2°, and falling gradually during the day was 95° at 6 P.M. It was feared that this might mean a recurrence of the hæmorrhage, but the character of the pulse (from 110 to 120, fairly full and regular) justified a favourable prognosis. On the 22nd the temperature for the first time was normal all day and continued so till Sept. 1st, when another relapse set in which lasted for 12 days. After this the patient made an uninterrupted though slow recovery. The general treatment throughout was fresh chlorine water and other intestinal antiseptics, sulphuric acid and opium to restrain the diarrhœa, and when [illegible] chloride of calcium in 20 grain doses. [illegible] by the [illegible] method [illegible] of the [illegible] without [illegible] india-rubber tubing about three feet long a Southey's trocar and cannula were attached, the other end being tied to the nozzle of an ordinary two-ounce glass male syringe from which the piston had been removed The whole was rendered aseptic by immersion in a solution of biniodide and subsequent flushing with hot sterilised water. The fluid was prepared by adding salt to water boiled in a tin kettle, brought to boiling point, and cooled to 100° F. It was introduced into the areolar tissue round the breast, the time occupied for 25 ounces being about ten minutes, only one insertion of the cannula being necessary on each occasion. An assistant holding the syringe uncovered in his left hand kept it about two-thirds full from the kettle held in his right hand. There are several advantages in this method, the most important being (1) the amount of fluid in the syringe can easily be seen; (2) by raising or lowering it the pressure can be increased or diminished; and (3) by firmly holding the syringe the temperature of the fluid is kept at, or about, blood heat. Any diminution in the temperature is at once noted and can be rectified by passing the kettle a few times over the flame of a spirit or paraffin lamp.

As a proof that, with ordinary precautions, there is little risk of local trouble in the above procedure it may be noted that in this case, although it was carried out five times (almost a gallon of fluid being injected), there was never at any time the least sign of irritation at the seat of injection.

THE POOR CHILDREN'S DINNER FUND.—His Majesty the King has sent a donation of £10 10s. to Sir William Treloar's Fund for entertaining poor children at the Guildhall (kindly lent by the Corporation of the City of London) and for sending 6000 Christmas hampers to poor crippled children This is the tenth year of the fund and the King has subscribed annually to it.

LONDON SCHOOL OF TROPICAL MEDICINE.—The entry of students at the London School of Tropical Medicine is the largest on record. About 30 post-graduate students have already joined for the autumn session, nearly half being sent from the Colonial Office, Foreign Office, and Indian Medical Service.

THE VALUE OF BLOOD EXAMINATIONS IN ABDOMINAL DISEASES.

BY C. J. NEPEAN LONGRIDGE, M.D., CH.B. VICT., M.R.C.S. ENG., L.R.C.P. LOND.,
HOUSE SURGEON, ST. GEORGE'S HOSPITAL.

THE results of hæmatological examination have been so satisfactory in the hands of those who practise it that an endeavour to extend the use of the method seems justified. The instruments required are (1) a suitable microscope, the best kind being that with a mechanical stage; (2) a Thoma-Zeiss hæmocytometer; (3) clean cover slips and slides; (4) a surgical needle; and (5) Toison's fluid and Jenner's stain. Even spreading of a blood film depends even more on the cleanliness of the cover slips than upon the dexterity of the maker. I clean them by boiling for 15 minutes in a solution of bichromate of potassium and sulphuric acid, washing in distilled water and alcohol, and keeping them in absolute alcohol. Toison's fluid is made up as follows: chloride of sodium, one part; sulphate of sodium, eight parts; glycerine, 30 parts; methyl violet, 0·025 part; and distilled water, 160 parts. This fluid should be frequently filtered Jenner's stain is a solution of a salt of methylene blue and eosin in methylic alcohol. It has the advantage of fixing as well as double staining the film.

The lobule of the ear is perhaps the most accessible and convenient situation from which to obtain the few drops of blood required. After cleansing the skin with ether the lobule is punctured with a surgical needle. The first drop of blood which appears is wiped away. The ear must on no account be squeezed in order to force out the blood. A second drop of small size is then allowed to adhere to the centre of a cover slip. On this a second slip is rapidly placed so that the drop of blood spreads out into a thin film between their two opposed surfaces. The two slips are then rapidly drawn asunder and the film is set apart to dry. A third drop is then allowed to run up the capillary red-counting pipette to the mark 0·5. Having obtained the exact quantity the conical end of the pipette is wiped free from blood and plunged below the surface of the Toison's fluid which is sucked up into the bulb to the mark 101. While doing this it is advisable to rotate the pipette on its long axis between the finger and the thumb to insure more thorough mixing of the blood with the fluid. This manœuvre results in obtaining a dilution of 1 in 200 of the patient's blood. In cases where the leucocytosis is probably slight the blood may with advantage be drawn up to the mark 1 0 in order to obtain a dilution of 1 in 100. The patient's ear may then be wiped clean and a wisp of cotton-wool may be applied to stop the bleeding. The rest of the examination may be performed away from the patient. The blood and fluid in the pipette are thoroughly mixed by shaking and an indiarubber band stretched over its ends affords an efficient protection against leakage or evaporation if the count cannot be at once performed. A drop of suitable size is then transferred to the counting chamber and a glass cover slip is applied. The corpuscles must then be allowed a few minutes to settle on the floor of the chamber. The interval may well be employed in cleaning the pipette. Some distilled water is drawn into the bulb and well shaken. This is replaced by some sulphuric acid and the pipette is again thoroughly washed with distilled water. After rinsing out with ether a final wash with absolute alcohol is given and the pipette is dried by sucking through it some hot air. It is most essential to prevent any trace of mucus or saliva reaching the pipette This can be efficiently done by blowing down a [illegible] tube containing a pledget of cotton-wool and a small [illegible] During the five minutes [illegible] the corpuscles will have settled in the chamber The red cells are then seen to be of a faint yellowish colour and the leucocytes to be stained a deep purple colour and somewhat highly refractile. I have been in the habit of counting three sets of 16 squares each in obtaining the number of red cells. To insure greater accuracy more squares should be counted and more than one drop of the mixture. For the purposes of this investigation, however, the number of red cells is of secondary importance, and I found that 48 squares counted gave a sufficiently accurate result for my purpose The number of cells in the

48 squares divided by six and multiplied by 100,000 gives the number per cubic millimetre in the blood.

In counting the number of white cells the method which is generally adopted is as follows. They are easily differentiated by the purple stain and their refracting character. An objective about $\frac{1}{6}$th or a Zeiss D is used with a low eyepiece. The ruled lines on the slide are then sought and the draw tube of the microscope is pulled out until the diameter of the field exactly corresponds to eight squares. The cubic contents of the field in view can then be easily calculated by the
a cylinder, since
metre and each sc
11 as $\frac{22}{7}$ the cubi
$\frac{4}{25} \times \frac{1}{10} = \frac{22}{875} = \frac{1}{79\cdot54}$. If then we count 50 fields and find an average of one cell per field we find that one cubic millimetre of the mixture contains 79·54 white cells; as the dilution was 1 in 200, the number of leucocytes per cubic millimetre of blood works out at 15,908. This method is quicker and more accurate than counting the leucocytes by means of the squares. The actual counting and calculation do not take more than a few minutes. Having thus found the numbers of red and white cells the films must be stained by means of Jenner's stain in order to arrive at a differential count of the leucocytes.

The four ordinary varieties met with are (1) polymorphonuclears (an irregular deeply staining nucleus with fine neutrophile granules); (2) lymphocytes (a small with deeply staining spherical nucleus and a little protoplasm); (3) hyaline cells (a large pale blue indented nucleus); and (4) eosinophiles (a pale blue nucleus, often double; large eosinophilous granules). Basophiles are so rarely met with that I have not taken them into account. 500 consecutive leuco*cytes are then counted*, half on each film, and the percentages are arrived at. In the few cases where the hæmoglobin was estimated Haldane's method was employed. Having thus arrived at a result of the blood examination, what can we draw from it? The basis of the matter is the fact that an increase of leucocytes accompanies acute inflammation. Typhoid fever at once occurs to our minds as an exception. Putting that aside leucocytosis is a sign of acute inflammation provided that (1) the resistance of the patient is capable of reaction; and (2) the intensity of the infection is capable of exciting reaction. The outcome of these factors means that a large leucocytosis will be provoked where the patient is in a high state of resistance and the infection is severe, while a patient in a low state of resistance will in the same circumstances exhibit but a feeble leucocytosis. The balance of these factors may later be of value in determining the prognosis of a case. I am not prepared to state that any definite relation exists between the amount of the leucocytosis and the intensity of the infection, but we can work upon the hypothesis that leucocytosis is the expression of nature's effort to counteract toxæmia.

In describing the effect on the blood generally it will be best to take each element in turn. I have not devoted any particular attention to the red cells or the amount of hæmoglobin. Da Costa, however, who investigated this question, came to the conclusion that in the average acute case there was a loss of 500,000 red cells and 30 per cent. hæmoglobin. The thickness of the fibrin network is, I believe, generally increased, but I cannot speak on this point from my own observation. The number of blood platelets is also increased; although I never counted them my impression is that I have seen more of them in cases with a large leucocytosis. The greatest alteration is found in the white cells. The normal number may be taken as 7500, of which from 60 to 75 per cent. are polymorphonuclears, from 20 to 30 per cent. are lymphocytes, from 4 to 8 per cent. are hyaline cells, and from 1 to 3 per cent. are eosinophiles. The great increase of the total number is of course the most prominent feature of the blood picture; almost equal in importance is the increase of the polymorphonuclear element; and, thirdly, the diminution of the eosinophiles and lymphocytes. The hyaline cells about keep their place. The polymorphonuclears and hyaline cells are the most active phagocytes in the blood.

In the accompanying table of blood counts in cases of appendicitis (Table I.) it was found on taking the averages of the acute and of the more or less chronic cases that the leucocytosis of the 22 acute cases averaged 27,990, of which 84·9 per cent. were polymorphonuclears and 0·4 per cent. were eosinophiles. Of the 14 subacute and chronic cases—I take the pathological condition as the basis of classification—the average leucocytosis was 10,614, of which 63·1 per cent. were polymorphonuclears and 2·1 per cent. were eosinophiles. The average count of five acute cases after operation and just before leaving the hospital was as follows: white corpuscles, 10,500; polymorphonuclears, 60·1 per cent.; and eosinophiles, 2·5 per cent.; or a condition almost exactly similar to the chronic cases.

There are certain special factors which have to be taken into consideration. Firstly, the influence of age. An analysis of the 22 acute cases gives the following results:—

TABLE II.—*Showing the Influence of Age upon Leucocytosis.*

Age.	No. of cases.	White corpuscles.	Poly-morpho-nuclears (per cent.).	Eosino-philes *(per cent.).*
Up to 20 years ...	6	26,100	85 8	0·3
From 20 to 30 years	8	24,320	83 9	0·35
„ 30 to 40 „	5	39,610	86·8	0·32
Over 40 years	3	21,160	80 8	0·8

The number of cases is, of course, too small for these results to be of much value, but so far as it goes the table shows that leucocytosis is most free between the ages of from 20 to 40 years and diminishes after 40 years. The physiological influence of age on leucocytosis is marked in the early months of life. At birth the number averages 18,000, sinks to 12,000 at the sixth month, and reaches the normal about the fifth year. The normal percentage of polymorphonuclears in infants is from 28 to 40 per cent. Marked leucocytosis also accompanies the later stages of pregnancy. An increase of from 2000 to 3000 leucocytes may occur after a large meal or exercise in a healthy adult.

Reference must be made to cases where there is little or no leucocytosis although the lesion is severe. First, there is a class of case in which the toxæmia is so intense that the reaction of the patient is overwhelmed. This class of case must, I think, be rare. Case 15 may, perhaps, be regarded as an example, as the lesion was very acute and extensive and the patient was a pale, ill-nourished boy, nine years of age. Secondly, a thick wall of inflammatory material surrounding a collection of pus may prevent the escape of the toxins which in some way cause the increase in the number of leucocytes. But in these cases valuable information may be gained from the differential count, a high percentage of polymorphonuclears indicating the possible severity of the lesion. Case 19 is a good example of this. The leucocytosis was only 14,000 on admission but 83 per cent. were polymorphonuclears. The count sank to 8600 in two days but on operation a small thick-walled abscess was discovered. In Case 31, however, where the blood picture was much the same, no pus was discovered but the parts were the seat of considerable recent inflammation.

Other cases which I might refer to are Cases 8 and 13

In the former, that of a spare man aged 51 years, the leucocytosis never rose above 11,500 and yet although there was no pus there was most extensive ulceration of the appendix. The clinical symptoms seemed to accord with the result of the blood examination. Case 13 is interesting. The girl was admitted to hospital in no very serious condition from the clinical point of view The leucocytes numbered 25,000 with 85 per cent of polymorphonuclears ; on the next day they were 27,300 and on operation a long and gangrenous appendix was removed The temperature fell, the wound healed, the bowels were opened, and no pain was felt The clinical picture was in all respects highly satisfactory. Yet nearly a week after the operation the leucocytes were 29 250. The evacuation of a deep collection of pus a few days later explained this apparent anomaly. Perhaps Case 25 may be noticed as an example of the influence of age.

Table III, showing blood counts in various abdominal affections, presents some interesting points. In Case 1 the somewhat high eosinophile count was probably caused by the presence of worms. In the first six cases, which were tuberculous in character, the number of lymphocytes is rather high. Cases 7 and 8 are high in eosinophiles which is said to be the distinguishing feature of the blood in hydatid cases. Case 9 is particularly interesting. The man was seized with sudden abdominal pain about 1.30. He was admitted to hospital in a very collapsed state and remained so for three hours; he then vomited slightly twice and there was a streak of blood in the vomit. The pulse rose from 80 to 100. The abdomen was rigid but not tender and there was some diminution in the hepatic dulness. At 6 30 reaction began to set in. At 7.30 I counted his blood but unfortunately omitted to make any films. The leucocytes, however, numbered 22,950. The abdomen was opened at 8 15 and free fluid and a little gas were found ; there was no lymph but the peritoneum was infected. A perforation of the stomach was found. The interest of this case is the fact that the leucocytosis occurred with such rapidity.

In conclusion, I must express my indebtedness to the medical and surgical staff of St. George's Hospital for their kindness in placing their clinical material at my disposal. I hope that the tables will serve as an illustration of the value and the shortcomings of blood examinations in abdominal diseases. I think that we cannot regard a leucocytosis as an absolute and infallible indication of the presence of pus, but as an indication of toxæmia its value appears to me very great. Although I do not think it possible at present to fix any definite relationship between the amount of the leucocytosis and the intensity of the toxæmia, yet the broad fact remains that an increasing leucocytosis is, other things being equal, the most scientific means at our disposal for gauging the increasing virulence of an appendicular infection. On the other hand, a decreasing leucocytosis is evidence of decreasing virulence or walling off of the toxic products.

I cannot do better than sum up the practical moral in the words of da Costa : "The surgeon who attempts to use the blood count in appendicitis as a definite pathognomonic sign will soon run afoul of diagnostic disasters ; but he who regards it as only a symptom invariably to be correlated with other equally, if not more, important clinical manifestations cannot fail to find this method of inquiry of signal value in routine clinical surgery."

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

AN UNUSUAL VESICULAR ERUPTION.

By JOHN REID, M.A, M D., C.M. ABERD.

IN February, 1902, I saw a young man who was supposed to be suffering from herpes of the face following influenza. There were a few vesicles about his neck, and the influenza—now bronchitis only—soon disappeared. The young man was of a healthy family and he had up to this date had no illness whatever. As the rash continued to spread over the body and extremities in the shape of vesicles or bullæ some were three inches long and about half an inch wide the disease was treated with antiparasitic remedies. The fluid of the vesicles was clear and it never contained pus at any stage ; even after the vesicles were pricked they never produced pus. They dried up into scabs or scales The large raw surfaces on the abdomen and other parts of the body made life uncomfortable for the patient whose health otherwise was good. The patient worked in a dairy and had much to do with chaff-cutting, the straw in many cases being described by him as containing "smut" The vesicular fluid, dried and examined under the microscope, also undried, contained what appeared to me to be *uredines*, or very like the growth obtained by me in November, 1885, from growing rust from wheat in connexion with a pneumonia epidemic. The disease improved by the treatment but was very stubborn.

Southfields, S.W.

SPONTANEOUS CURE OF AN UMBILICAL FÆCAL FISTULA.

By GOPAL R. TAMBE, M.A., B.Sc., L.M. & S.,

STATE SURGEON, INDORE.

ON June 14th a man, aged 45 years, a Mahomedan, came under my care at the Maharajah Tukoji-Rao Hospital in Indore, Central India. He suffered from a fluctuating tumour at the umbilicus, which latter bulged out for a distance of one and a half inches from the abdominal wall and presented a small opening surrounded by exuberant granulations. On gentle pressure being made a drop of purulent discharge escaped from the opening. I therefore afterwards administered chloroform and cautiously opened the abscess on a director, when to my surprise I found three solid masses resting on the floor of the cavity. Much pus was washed out and the cavity was stuffed with iodoform gauze. Further examination of these three masses under the microscope and otherwise showed that they consisted of fæcal matter and had apparently escaped from a fæcal fistula which had subsequently become closed. The history given by the patient was that the abscess had been of a [illegible] previously to noticing it he had n[illegible] trouble or inconvenience. Consi[illegible] involved in perforation of the intestine and the great amount of care and attention required in surgical operations on the intestine, the cure imperceptibly effected by natural processes in this case is remarkable.

Indore, Central India.

NOTE ON THE INTERNAL ADMINISTRATION OF FORMALIN IN CASES OF PUERPERAL FEVER.

By CHARLES STEELE, M.D. DURH., F.R.C.S. ENG.

SOME time ago I saw a note of seven cases of puerperal fever having been treated by hypodermic injections of formalin with remarkable and rapid recoveries. I decided to try the method in any suitable case, but as I saw no detailed statement on the subject in the medical journals I was careful to use the drug only in small doses. The following are the results.

CASE 1.—The patient, the mother of three children, a delicate woman and very susceptible to the influence of drugs, miscarried on Feb. 4th, 1903, being in fair health at the time and only six months pregnant. The conjectures offered to me as to the cause of this occurrence at such an unusual period did not satisfy me; with this exception, that she had slipped off her chair and suddenly bent forwards a few days before it took place. She did well for a week and then had a rigor followed by a temperature of 102° F., slight odour in the lochia, and pain in her uterus. I prescribed one minim each of formalin and tincture of aconite in an ounce of water, every hour at first, gradually lengthening the intervals as improvement took place. She liked to take this medicine as it gave a comfortable, warm sensation in her stomach, spreading through the abdomen and the system and induced a cheerful feeling of its "doing good." [illegible] I gathered to be due to undue ex[illegible] needs of the system. Steady [illegible] relapse occurred after two weeks but soon yielded to treatment. Weakness was felt for altogether five weeks but complete recovery took place. She was reluctant to give up the formalin on account of the comfort which it induced.

CASE 2.—The patient, who was the mother of a boy, two and a half years old, was confined at full term after four hours of steady labour on May 13th, 1903, and did remarkably well for four days. On the afternoon of the fifth day her husband came to tell me that she had a rigor and a temperature of 104° F. and that she looked very ill. I went at once and found the temperature to be 106°, the pulse 120, and the respirations 36. The lochia were normal and lactation was uninterrupted. No cause for the attack could be found. She had an excellent nurse There were profuse saturating perspiration and severe headache; her lips were blue and on the next day the finger-tips were blue also. Three grains each of antifebrin and antitoxin were administered every hour until the temperature dropped, then these drugs were given less frequently. I also gave one minim of formalin in an ounce of water every half hour at first and then every hour. It should be mentioned that five days after her first confinement she had a slight feverish attack which yielded quickly to a few doses of Dover's powder (five grains) and also that about a year previously she had an extremely prostrating attack of influenza which depressed the action of the heart to an anxious extent, but from which she steadily recovered.

This patient expressed just the same feeling of comfort and warmth in the stomach, spreading through the abdomen and the system and making her feel altogether better, as did the previous patient. There was no cough, bronchitis, pleurisy, or pneumonia, or any other mischief. The urine was condensed for a few days owing to the free perspiration, but it was otherwise normal as were also all the functions, including the nursing of the child, which was carried on without injury to herself or the baby. She is now (July) perfectly well. On the second day I went prepared to inject antistreptococcic serum, but was thankful to find it unnecessary, as the remedies which I have described had sufficed.

BOLINGBROKE HOSPITAL, WANDSWORTH COMMON.

A CASE OF PERFORATED DUODENAL ULCER; OPERATION; SUBSEQUENT DEVELOPMENT OF SUBHEPATIC ABSCESS; RECOVERY.

(Under the care of Mr. HAROLD BURROWS.)

THE patient, a man, aged 24 years, was admitted to the Bolingbroke Hospital on March 4th, 1903, with symptoms of perforative peritonitis. On the previous night at about 11.30 he was playing billiards and as he stooped down to make a stroke he was seized with a sudden severe pain in the right hypochondrium. He felt sick and faint and was given some brandy which neither increased the pain nor made him feel better. Shortly after this the patient began to retch and to vomit, these symptoms, together with severe pain in the abdomen, continuing up to the time of the operation; in fact, the vomiting was so frequent that a diagnosis of intestinal obstruction had been suggested. The patient's last meal before the onset of the attack had been at 6 P.M., five and a half hours previously, and had consisted only of three cracknel biscuits and some tea. He stated that he had always enjoyed good health except for indigestion, from which he had suffered for years. He described it as pain or "a feeling of weight on the stomach" coming on about one and a half hours after a meal and always relieved for a time by taking more food. On examination in the ward the patient was evidently in acute pain. He was lying on his back with the legs extended; his expression was one of great anxiety and he was hiccoughing and frequently retching. The abdomen showed the usual characters of general peritonitis with these special points—viz., the pain and tenderness were most marked in the right hypochondriac region, rigidity of the abdominal muscles was more marked above the umbilicus than below, and the right rectus muscle was distinctly more rigid than the left.

Laparotomy was performed at 2.30 P.M., 15 hours after the onset of acute symptoms. A vertical incision was made through the upper part of the right rectus three-quarters of an inch from the middle line. As soon as the peritoneum was opened odourless gas escaped, together with some fluid which resembled weak tea with milk. On raising up the liver and pressing down the transverse colon a perforation about one-sixth of an inch in diameter was found on the upper surface of the duodenum near the junction of the first and second portions. Bilious material was oozing through the opening. The duodenum and neighbouring parts were coated with plastic lymph. No induration could be felt in the neighbourhood of the ulcer. The peritoneum was taken up at three points beyond the margin of the ulcer by a fine silk ligature and the included area was then inverted and the suture was drawn tight and knotted. Some difficulty was experienced at this stage on account of the awkward position of the ulcer and the constant oozing out of bilious material which prevented a good view of the seat of the lesion. When this had been accomplished the surrounding peritoneum was swabbed dry, an indiarubber drainage-tube with a gauze wick inserted down to the site of the perforation, and the abdominal wound sutured. The patient recovered from the immediate effects of the operation but afterwards developed a subhepatic abscess which was opened and drained through the right loin on April 14th, 41 days after the first operation. After this convalescence was uninterrupted. When last seen, on August 10th, the patient was in good health and stated that he was quite free from pain or discomfort after food.

Remarks by Mr. BURROWS.—The above case is of some interest because comparatively few cases have been recorded where perforation of a duodenal ulcer has given rise to symptoms sufficiently characteristic to allow of a correct diagnosis being made previously to operation or necropsy. In this instance, fortunately, the symptoms both before and after perforation pointed rather definitely to the duodenum as the site of the lesion.

ST. MARY'S HOSPITAL, MANCHESTER.

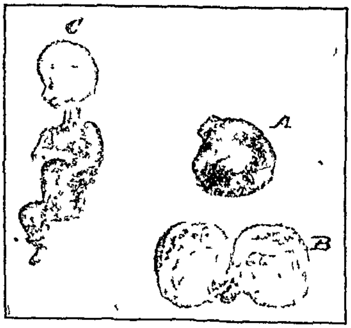
A CASE OF ECTOPIC GESTATION REMOVED BY ABDOMINAL SECTION WITH A DERMOID TUMOUR OF THE EXTREMITY OF THE LEFT TUBE.

(Under the care of Dr. D. LLOYD ROBERTS.)

THE patient was a married woman, aged 29 years, who was admitted into St. Mary's Hospital, Manchester, on April 23rd, 1903. Her menstrual history was as follows. The first menstruation occurred at 12 years of age and the last on Jan. 1st, 1903; it had previously been regular every three weeks; the duration was five days, the amount being small. There had been amenorrhœa for four months. She had had no previous pregnancy. She had had pains in the stomach on and off since the last period. The pains came on very severely on the day of admission; the patient was sick but did not faint. During the last month she had had several attacks of pain and collapse, two of the attacks having occurred within the last four days. On admission the patient was exceedingly blanched; she had much pain, with considerable tenderness. There was an indefinite swelling in the lower part of the abdomen, especially on the right side; dulness was present in both flanks. Per vaginam the vaginal orifice and the walls were normal; the os and the cervix were also normal. There was some bulging in the posterior and right fornices; the uterus was rather heavy. There was a semi-cystic swelling on the right side about as large as an emu's egg.

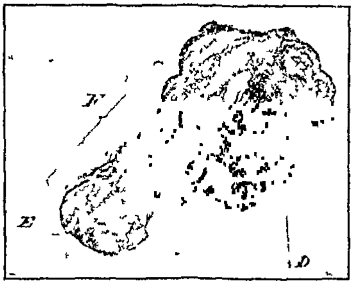
Operation was performed on April 24th. On opening the abdomen a large quantity of dark-coloured blood escaped which with a considerable amount of laminated clot and a fœtus about three inches long were removed. The right tube was then found to be ruptured, with apparently the placenta protruding. The tube and the ovary were removed. Attached to the left tube was found a small rather firm tumour about one and a quarter inches long and three quarters of an inch broad, which was removed (see Figs 1 and 2) The abdomen was then washed out with sterilised water. The abdominal wound was brought together by a single row of silkworm gut sutures The dressing consisted of aseptic gauze and cotton-wool secured with broad strips of plaster The temperature rose to 99 8° F. on the evening of the operation, after which it was never above 99 6°. The ligatures were removed on the eighth day and the subsequent recovery of the patient was uneventful

FIG 1.



A, Small teratoma as removed *B*, The same in section *C*, Fœtus

FIG 2.



D, Ruptured tubal sac. *E* Ovary *F*, Pedicle composed of severed broad ligament

Remarks by DR LLOYD ROBERTS —Naturally it may be asked why vaginal cœliotomy was not performed and the sac and its contents removed through the orifice so made I should certainly prefer this route if the sac were fixed, adherent, and applied to the upper wall of the vagina and the floor of the pelvis But in cases similar to this one, where the sac has burst and where the contents have escaped into the pelvic cavity, and where the ovum has separated from its placental attachment and is floating along with blood, fluid, and débris in the peritoneal cavity, I prefer the abdominal route Moreover, sight as well as touch is of material help to the operator when dealing with complicated cases of ectopic gestation Also as the separated ovum in this case had ascended into the abdominal cavity it would have been very difficult to find and to extract it by the vaginal route

A word as to the question of irrigation *versus* cleansing the abdominal cavity with sponge or swabs of cotton wool. When numerous small clots and a large amount of fluid are present I much prefer irrigation with sterilised water to sponging as it is well nigh impossible to remove the fluid and clots from the recesses behind and about the intestines with the sponge.

Another point of interest in this case was the small tumour which was attached to the fimbriated extremity of the other Fallopian tube and proved to be a small teratomatous growth, containing bone, cartilage, connective tissue, and necrotic masses which, so far as can be judged, were of epithelial origin Dr W E Fothergill, who kindly examined the tumour for me, says that it must be regarded as a teratomatous growth and is probably a dermoid cyst No chorionic villi were found in it

DURHAM COUNTY HOSPITAL

A CASE OF FOREIGN BODY IN THE URETHRA

(Under the care of Mr S W PLUMMER)

A YOUNG man, aged 22 years, was admitted to the Durham County Hospital on June 9th, 1903, complaining that on Feb 5th last he had passed down his urethra a hat pin of about the length of his finger His mental capacity was weak and he had often been in trouble with the police for minor offences. Two years previously he had been operated on in the hospital for the radical cure of hernia when his behaviour gave great trouble On examination the hernia was completely cured Passing a sound into the bladder a foreign body was easily felt in the prostatic urethra, and when the sound was passed fully into the bladder it distinctly gave the impression that the foreign body projected into the bladder As the man said he had passed the pin head first into the urethra it was decided to open the bladder suprapubically, feeling that if pressure were made on it by the perineum it would only be forced still further into the bladder This was done but no trace of the pin could be felt on digital exploration A median lithotomy staff was then passed and the urethra was opened in the perineum and after some little difficulty a steel hat pin two and five eighth inches in length with a large *black glass head was extracted*

Remarks by Mr PLUMMER —On a previous occasion[1] I recorded in THE LANCET a case of removal from the male bladder and urethra of a hat-pin five inches in length The Editors then gave some references to similar cases The above notes of another instance may be of interest The chief point in this case is the length of time (over four months) during which the hat-pin had been in the urethra without causing any trouble , indeed, when the patient applied for admission he did not complain and only stated it was there Mr Brunel's manœuvre of reversing the pin could not in this case be carried out The urethral wound was sutured and the after treatment directed to the suprapubic cystotomy.

Medical Societies.

PATHOLOGICAL SOCIETY OF LONDON.

Fractures in Skeletons of Large Apes —Cancer on Nerve or Trophic Areas —Cartilaginous Body from the Knee joint —Prostatectomy —Congenital Sacral Tumour removed from a Girl, aged one year

A MEETING of this society was held on Oct 20th, Mr RICKMAN J GODLEE, the President, being in the chair

Mr W L H DUCKWORTH read a paper entitled Notes on Fractures and other Skeletal Lesions in Anthropoid Apes " and illustrated his communication by specimens and by lantern slides He said that in the course of observations on the skeletons of anthropoid apes he had been struck by the large number of instances of bony lesions presented by these animals The examples shown consisted principally of cases in which the natural repair of a fractured bone had been attended by an excessive production of callus Pathological bone formation due to osteo arthritis and to periostitis of obscure nature was also met with In conclusion, it was pointed out that the large apes were much more liable to fractures than were the smaller apes and that among the larger apes the most arboreal example—viz , the orang outang—was the most susceptible This would indicate that the orang-outang had increased in size to the utmost limit appropriate to a mammal with an arboreal habitat and that it was thus very delicately adjusted to its environment This no doubt explained its limited area of geographical distribution. Secondly, anthropoid apes in the wild state were able to survive very terrible injuries consequent on traumatic lesions. Thirdly, the investigation of such pathological specimens had important bearings on the particular case of the femur which was described as that of an intermediate form between the apes and man and which bore a large exostosis springing from the linea aspera.

---

[1] THE LANCET, Nov 7th, 1891, p 1039

Mr. G. L. CHEATLE said that in a former communication to the society he had pointed out that Rodent Ulcers and Squamous Epithelioma occupied certain areas which he thought were nerve areas and sensory nerve areas. He wished now to amplify that point. He alluded to the difficulty of demonstrating squamous epithelioma occupying nerve areas, a difficulty which he believed could be explained by the separation of cells from the primary growth and hence complicating matters by becoming secondary deposits. He wished further to strengthen another observation which he had made—viz., that the incidence of cancer frequently occurred on those points at which a nerve became cutaneous—and to show that the genesis of carcinoma was very frequently associated with points which Dr. H. Head had described as maximum points, and here again a difficulty was experienced in bringing into line squamous epithelioma with rodent ulcer. He divided his paper into two parts: (1) the spread of cancer in nerve areas; and (2) the incidence of cancer on Head's maximum points. In illustration of these points he showed a number of lantern slides of cases of rodent ulcer, proving that the growth tended to occupy certain nerve areas and also that the growth tended to start in Head's maximum points. On the face it might be asserted that these points corresponded to embryonic clefts, but such an argument could not be advanced against the growth on the trunk which also originated in Head's maximum points.

Mr. RAYMOND JOHNSON brought forward a specimen of a Pedunculated Cartilaginous Body removed from the Knee-joint. The portion of the synovial membrane to which the pedicle was attached was also removed and the interest of the specimen consisted in the presence of numerous nodules of hyaline cartilage in the synovial membrane around the attachment of the pedunculated body. It thus demonstrated in an unusual way the formation of such a chondroma by a growth of cartilage in the synovial membrane. A specimen of a Cartilaginous Tumour removed from a Tendon Sheath in the Hand was also exhibited. No record had been found of a similar specimen.

Mr. S. G. SHATTOCK discussed certain anatomical points in connexion with the operation of Prostatectomy from an examination of a series of specimens which had been presented by Mr. P. J. Freyer to the Museum of the Royal College of Surgeons of England. The two questions upon which controversy had arisen were: (1) how far the prostatic portion of the urethra was preserved, and (2) was the whole of the prostate removed. Much of the interest in regard to the urethra had now gone, since its preservation was no longer regarded as of any moment. The subject of the urethra had to be considered firstly in the case where the gland was removed with its circumference entire, and secondly, when the gland was divided in front of the urethra with the definite purpose of saving the canal. As an example of the first Mr. Shattock selected the eighth case recorded by Mr. Freyer in the *British Medical Journal*, Feb 1st, 1902, a case in which Mr. Freyer thought that the urethra had been preserved. Here, after the gland was detached all round, with the catheter passing through its axis, the whole mass, on counter pressure being made from the rectum, was suddenly propelled into the bladder and it was thereupon noticed that the catheter was covered by the urethra for about two inches from the triangular ligament; this portion of urethra was regarded by Mr. Freyer as prostatic, off which the gland had been drawn like a bead from a thread. The specimen showed beyond the anterior end of the gland a cord-like process which was viewed by the operator as the pubo-prostatic ligaments. A minute examination of this, however, showed it to be urethral mucosa covered on one side with columnar epithelium and continued without solution of continuity into the bore of the gland. This must be regarded as membranous urethra avulsed in connexion with the prostate and this, Mr. Shattock imagined, was the urethra felt on the catheter after the gland had been displaced into the bladder and whilst the finger was still in front of, or on the distal side of, the gland. In a second class of cases the gland was parted in the mid-line in front of, or above, the urethra with the object of peeling the latter off and afterwards completing the removal of the enucleated gland by displacing it into the bladder. As an example, in Case 9 of Mr. Freyer's lists this was thought to have been carried out, but examination showed that except at the anterior end the urethral and vesical mucosa remain on the enlarged gland, the depth of the canal being, as usually the case, largely increased. Mr. Shattock showed a like condition in an enlarged prostate removed by Mr. A. Pearce Gould where a similar attempt was made to preserve the urethra and where almost the whole of the mucosa remained, in places so thinned that it could hardly be raised on dissection, yet microscopically showing a rosary of prominent epithelium and traceable without interruption to the flaps of thicker mucosa remaining on the vesical surface. In fact, the object aimed at in such circumstances was so incompletely attained that it could not, properly speaking, be said to have been carried out, such extensive tracts of thinned urethral mucosa did examination disclose adhering to the deepened bore of the gland. Passing on to the other question, how much of the gland was removed, Mr. Shattock had selected the most clearly extirpated of all Mr. Freyer's specimens (Case 28, *British Medical Journal*, April 18th, 1903) The gland was removed with its circumference quite entire. After hardening, it was cut completely through at right angles to the axis of the urethra and microscopic sections were made of the entire area, midway between the upper, the vesical, and the lower ends. To prevent confusion it was necessary to use terms in the same sense as Mr. Freyer. By the "sheath" was to be understood the fibrous investment furnished by the recto-vesical fascia; by the "capsule," the fibro-muscular cortex which was directly continuous with the stroma of the gland, but into which the gland tissue did not itself penetrate. The transverse section in Mr. Freyer's specimen displayed a well-marked cortex of unstriped muscle fibre completely surrounding the glandular mass. It was at once obvious that what had been carried out was not the mere enucleation of an adenomatous formation. The surface of a prostatic adenoma, like that of others, was smooth and lobulated or tuberous. In the various other of Mr. Freyer's specimens also the same held true. The mass removed was invested with a cortical zone of fibro-muscular tissue, through rents or bosses in which the smooth tuberous adenomatous mass of the enlargement presented itself to view. Mr. Freyer's operation, therefore, was a prostatectomy. But was it as *complete* a prostatectomy histologically as it was from a surgical aspect? Did the line of enucleation absolutely and everywhere pass beyond the limits of the gland tissue? A critical study of the muscular cortex in Mr. Freyer's specimen showed that this was not the case. For long distances the cortex was solely of plain muscle concentrically disposed, but here and there were the unmistakeable flattened masses of gland tissue and so involved were these in the line of enucleation that one could not but believe that others had remained behind. For in this, as in the others of Mr. Freyer's specimens, the transversely fasciculated character of the surface of the capsule showed that the line of enucleation was not beyond but through it. From the histological side, therefore, Mr. Shattock thought that prostatectomy was in most cases incomplete. A complete prostatectomy, in short, could hardly be verified in this strict sense except by the microscopic examination of the parts left behind.

Mr. H. J. CURTIS read a short paper on a case of Congenital Sacro-coccygeal Tumour successfully removed from a girl, 12 months old. It formed a prominence, surmounted by a tuft of fair hair, over the lower part of the right border of the sacrum and coccyx. The greater part of the tumour lay between these bones and the rectum, clearly visible at the operation. The tumour consisted of a series of cyst-like cavities imbedded in a mass of fat. The cysts were really tubules more or less dilated. In the fresh condition they were filled with clear, viscid, mucoid fluid. Microscopically the "cysts" were seen to be lined by a single layer of large, non-ciliated, fully developed, columnar epithelium cells. To such tumours Bland-Sutton had applied the name "thyroid-dermoid," in reference to the closed spaces lined by cubical or columnar epithelium containing mucoid fluid. Like Middledorpf's case the tumour contained connective tissue, mucous membrane with characteristic follicles, submucous tissue, and longitudinal and circular layers of muscle fibres; in other words it clearly represented a portion of bowel. In addition, areas of cartilage and of epithelial or epithelioid cells massed together without intervening stroma existed. The epithelial element in all probability was the remnant of the undifferentiated embryonic tissue from which the tumour itself originated.

OBSTETRICAL SOCIETY OF LONDON.

Extra-Uterine Gestation.—Ruptured Tubal Gestation.—Abdominal Pregnancy.

A MEETING of this society was held on Oct. 7th, Dr. EDWARD MALINS, the President, being in the chair.

Mr. JOHN D. MALCOLM read a paper on an Operation for Extra-Uterine Gestation between the Third and Fourth Months of Gestation, with Removal of a Living Fœtus. The patient, a healthy woman, was married on Oct. 9th, 1899, at the age of 23 years. In the middle of April, 1900, she felt depressed, menstruation became irregular, and she had attacks of pelvic pain, with nausea, commencing in May. On July 17th a large abnormal mass was felt behind the upper part of the vaginal wall, nearly filling the pelvic cavity and rising to about half-way between the pubes and the umbilicus. The uterus was somewhat enlarged, was dragged up, and was pushed over to the left side of the pelvis. On July 18th an incision was made in the middle line above the pubes, a small collection of pus being opened, and through it the amniotic sac was evacuated. A fœtus of between three and four months' development was extracted without opening the peritoneum and the placenta was felt with an extensive attachment over the right side and floor of the pelvis. The cavity was packed with iodoform gauze and no attempt was made to remove the placenta. The latter remained alive and there were frequent and sometimes profuse hæmorrhages when the gauze packing was changed between July 24th and August 10th. On the latter date an attempt was made to break up and to get away the placenta. A small piece was torn off but hæmorrhage was so alarming that the wound had to be packed immediately. The placenta was killed by this procedure and there was hardly any blood los [illegible] y bit of the placenta had to be [illegible] sues and its removal was not co [illegible] There was an inflammatory attack with some intestinal difficulty in September and the wound did not finally heal until the middle of December. The patient was now in perfect health.

Dr. C. H. G. LOCKYER contributed a paper on a Case of Ruptured Tubal Gestation in which the ovum continued to live for about four months, the gestation sac becoming implanted on the omentum. The symptoms began with uterine hæmorrhage and the passage of a (?) decidual membrane on Dec. 27th, 1902; this was after a period of amenorrhœa dating from the end of October (eight or nine weeks). Signs of internal hæmorrhage appeared on Jan. 11th, 1903 (about the eleventh week of gestation). A swelling in the left ovarian region was palpable on Jan 20th. An operation was performed on Feb. 11th and death took place 24 hours later. The primary tubal rupture occurred through the upper, or peritoneal, aspect of the tube and the fœtus escaped into the abdominal cavity; chorionic villi gained immediate attachment to the lower edge of the omentum, which approximated, and presumably was adherent, to the tube prior to rupture. The omentum enveloped the gestation products and soon shut them off from the general peritoneal cavity. The secondary gestation sac so formed seemed to have remained intact from Jan. 11th to Feb. 5th. On Feb 9th, the time of the third crisis, the fœtus probably escaped through a rent in the amnion, since it was found in the peritoneal cavity two days later at the time of the operation. The way in which implantation on to the omentum took place was analogous to that which occurred when, the rent having been below, the villi grew out between the layers of the broad ligament, but events proved that the risk of secondary rupture was greater when the sac was formed of omentum than when the envelope was composed of the broad ligament folds.

Dr. J. B. HELLIER brought forward the report of a case of Abdominal Pregnancy secondary to a Partially Ruptured Pregnant Tube.

Dr. G. E. HERMAN said that he could not agree with Mr. Malcolm's recommendation of prompt operation in all cases of ectopic pregnancy in which the fœtus was living, whatever the period of pregnancy. In the first half of ectopic pregnancy certain dangerous events, such as rupture of the tube or of the gestation sac, were frequent, but dangerous accidents of any kind were rare in the second half of ectopic pregnancy. When the patient got to term spurious labour came on and at this time the patient was in practically no danger. Then the child died, the liquor amnii was absorbed, and, finally, after an interval, the length of which was not yet exactly known, the placenta became thrombosed. The patient was as a rule in no danger until suppuration took place, but suppuration might not occur at all and the patient might remain in good health to the end of a long life, subject only to the inconvenience of an enlarged abdomen. He therefore thought that in the second half of ectopic pregnancy with a living child the safer course was to wait until symptoms of suppuration had begun.

Dr. W. F. V. BONNEY said that within the last few months two similar cases had come under his own notice. Both these two patients were operated on by Mr. J. Bland-Sutton and an enormous retroperitoneal collection of blood was found in the first, whilst from the second, who had also suffered from two months' amenorrhœa, a perfect and unruptured secondary abdominal sac, containing a living fœtus of between four and five months, was removed with a successful result.

Dr. AMAND J. M. ROUTH gave some further details of the history of Dr. Lockyer's patient. She had had three attacks of collapse from internal hæmorrhage with amenorrhœa for nine weeks. The diagnosis of extra-uterine gestation was made from the history and the physical signs. It was assumed that it was a secondary intraperitoneal pregnancy after tubal rupture owing to the tumour being entirely distinct from the retroverted uterus. At the operation the placenta was found to be already separated on its central maternal surface and adherent at several parts of its circumference to the omentum and the broad ligament. After its removal there was a profuse general capillary hæmorrhage from all the underlying structures. This was at once arrested by firmly applied gauze pressure. As the anæsthesia passed off uncontrollable vomiting ensued and she died from exhaustion in 24 hours. Dr. Routh asked for the experience of those present regarding the persistent amenorrhœa in this case and the one mentioned by Dr. Bonney instead of the usual metrorrhagia. Was it peculiar to these cases of secondary intraperitoneal pregnancy?

Specimens were exhibited by Dr. W. E. BATCHELOR, Dr. H. R. SPENCER, Mr. J. H. TARGETT, and Dr. A. W. SIKES.

HARVEIAN SOCIETY OF LONDON.

Exhibition of Cases.

A MEETING of this society was held on Oct. 15th, Dr. W. WINSLOW HALL, the President, being in the chair.

Dr. HERBERT TILLEY showed a man, aged 49 years, upon whom he had *operated five and a half years ago for* Squamous-celled Epithelioma of the Right Vocal Cord. The only symptom for the relief of which the patient applied to the hospital was "hoarseness" of two months' duration. Laryngoscopic examination revealed a well-defined pale nodule occupying the anterior two-thirds of the right vocal cord. It was of the size of a small horse-bean and surrounded by a slight zone of congestion. The vocal cord upon which it grew was *motionless* in phonation. This fact, coupled with the appearance of the growth, determined the diagnosis of epithelioma. There were no enlarged glands in the neck. The operation consisted of a preliminary tracheotomy, followed by insertion of Hahn's tampon cannula in order to prevent the blood passing into the lungs during the operation. The thyroid cartilage was divided in the middle line and the halves were held apart while the diseased cord with the ventricular band was completely dissected out. Finally, the halves of the thyroid cartilage were brought into accurate apposition by a catgut stitch, the external wound was sutured for three-quarters of its length, and the cannula was removed from the trachea. The patient made a rapid recovery. The points of interest in the case were that the hoarseness was the only symptom of such a grave disease and the excellent voice which the patient then possessed. The place of the original vocal cord had been taken by a cicatricial band forming a sort of fixed false cord. Dr. Tilley laid stress on the importance of an early diagnosis in these cases. If the radical operation was performed early in these intrinsic cases a very high percentage of cures (compared with malignant disease in other parts of the body) could be obtained.—Dr. ATWOOD THORNE would have liked to hear more with regard to the microscopical results.—Dr. TILLEY replied that the sections of the growth exhibited at the Laryngological Society showed it to be a squamous epithelioma with cell nests.

Dr. WILFRED J. HARRIS showed a man, aged 40 years, who three years ago fell a distance of about four feet on to his left shoulder causing Immediate Paralysis of his Arm. This was followed by wasting of the deltoid, infra-spinatus, biceps, brachialis anticus, and supinator longus, and by anæsthesia of the thumb and index finger. No improvement occurred after treatment by galvanism. An operation by Mr. V. Warren Low in June last on the upper roots of the brachial plexus showed that they were buried in scar tissue. This was cleared away and stimulation of the roots by faradism showed the fifth root to be quite destroyed, while the sixth root gave good reactions. The fifth nerve was then cut across and sutured into a nick made in the sixth root. Immediate improvement resulted in the anæsthesia of the thumb and finger. The galvanic reactions of the affected muscles have also since improved.—The PRESIDENT asked if the man was likely to recover complete power in the limb. —Dr. HARRIS replied that muscular power might begin to return after six months.

Mr. E. LAMING EVANS showed a case of Spina Bifida in a child, aged three years, involving the third, fourth, and fifth lumbar vertebræ and the whole of the sacrum. Control over the bladder was absent. Associated with the trouble was a talipes equino-varus involving both feet, of congenital origin The electrical reactions of the muscles of the legs were normal. The skin of the feet was atrophic. Mr. Evans considered the case to be one of meningo-myelocele and recommended no operative interference except for the correction of the deformity of the feet —Mr P. L. DANIEL suggested arthrodesis on the ankle- and knee-joints so as to fix the joints and to enable the child to walk.—Mr. EVANS replied that as there was good muscular power in all the muscles of the leg and as the child had already walked upon her feet in the deformed position arthrodesis did not seem called for. The child would be able to walk well with a plantigrade foot after the equino-varus deformity had been corrected

Mr. LAMING EVANS also showed a woman, aged 21 years, with Double Pes Cavus and other Deformity of the Feet which had existed as long as she could remember. No history of an infantile paralysis could be obtained. Situated over the eleventh and twelfth dorsal spines was a swelling one and a half inches in diameter over which the skin was freely moveable, tender to the touch, and not attached to the underlying tissues by any definite pedicle. Hypertrichosis was absent. Mr. Evans suggested the possibility of the swelling being connected with the meninges and that the condition of the feet was dependent upon some spinal cord mischief of congenital origin.

Mr. DANIEL showed a man suffering from Tabes Dorsalis with a perforating ulcer at the base of the second and third toes, causing absorption of the phalanx of the third toe. He called attention to the fact that cases of untreated mild syphilis and cases of "soft sore" were frequently followed by tabes and ulcer many years after infection. He thought that "soft sores" with tendency to spread, to infect by contact, and to produce enlargement of the glands of considerable acuteness were all probably syphilitic and should be so treated. Malignant change in perforating ulcer was rare; and this fact was not in accord with the idea that nerve control was a great factor in cancer distribution and causation. The loss of nerve control in perforating ulcer in association with the chronic nature of the wound should lead to frequent malignant change on the "nervous theory."—Mr. F. JAFFREY suggested treatment by oxygen, obtained by applying peroxide of hydrogen for half an hour daily. At other times the ulcer should be protected with boric lint.—Dr. HARRIS considered these ulcers to be due not merely to pressure but to be also of trophic origin.—Mr. LAMING EVANS suggested removal of the ulcer and diseased bone, as thereby relapse was more likely to be avoided. He considered that the trophic element entered largely into the causation of these ulcers.—Mr. DANIEL, in reply, said that he had no belief in trophic [illegible] instances, in removal of the Gasserian ganglion, [illegible] which followed was always due to sepsis and [illegible]. As regards treatment he proposed to [illegible] the toe and the diseased tissues.

[illegible] showed, for Mr. T. CRISP ENGLISH, an old man with an enormous Ventral Hernia, apparently containing a large proportion of the abdominal contents. In consequence of the absence of Mr. English no notes on the case were forthcoming.

MEDICO - PSYCHOLOGICAL ASSOCIATION. — The autumn meeting of the Northern and Midland Division of this association was held on Oct. 9th at the Northumberland County Asylum, Morpeth, by the kind invitation of Dr. T. W. W. Macdowall.—The members first visited one of the villas recently built to the east of the main asylum block. It provided for 40 male patients. The accommodation given was excellent and there was a great sense of freedom, there being no locks and the patients being free to go in and out at will. The cost was very moderate, £120 per bed including furniture. Dr. Macdowall, the president of the meeting in the afternoon, in giving an account of the new departure, claimed that about 25 per cent. of pauper patients could be accommodated in villas similar to those which the members had seen and that it was much less expensive and much more comfortable for the patients than a large asylum building. He further claimed that chronic patients improved mentally on removal to the more homely surroundings provided in small houses of this description.—Dr. A. W. Campbell of Rainhill gave a demonstration of Histological Studies of Cortical Localisation. He gave a detailed account of a long series of researches into the structure of the cortex and showed the great value of this branch of study in correcting and confirming the results of experimental investigation. He showed a beautiful series of drawings of sections of the cortex and demonstrated the differences in structure between the different areas. He showed that his results confirmed the previous conclusions of Mr. W. Bevan Lewis which at one time had seemed to be in opposition to experimental results. It had now been shown that the conclusions arrived at by the histological investigation as regards the limits of the motor area had been fully confirmed. The President, Dr. W. F. Menzies, and Dr. J. Middlemass congratulated Dr. Campbell on his brilliant research and discussed some of the points raised and Dr. Campbell replied.—Dr. Middlemass exhibited a case of Development of General Paralysis [illegible] in which the history and signs of congenital syphilis were very clear. He pointed out the gradual growth in opinion that general paralysis was always due to syphilis, inherited or acquired.—The President, Dr. W. M. A. Smith, and Dr. Menzies joined in the discussion which followed.—Dr. Bedford Pierce showed an automatic fire alarm box containing an emergency key which it which had been fitted at Throxenby Hall, Scarborough, a branch of the Retreat. He claimed that this automatic arrangement of alarm and emergency key was a great safeguard in case of fire and it also prevented the key being used by unauthorised persons.—Dr. Norah Kemp read notes of a case in which thyroid treatment repeatedly produced temporary success. The case was a very striking one: a chronic maniac [illegible] and [illegible] years, the patient had had a lucid interval on [illegible] a few days on four occasions following the administration of thyroid extract.—The President, Dr. Middlemass, Dr. Smith and Dr. Pierce joined in a discussion and all agreed that on the whole the results of thyroid treatment were disappointing and the President pointed out the real danger of cardiac failure from using the drug.

DERMATOLOGICAL SOCIETY OF LONDON.—A meeting of this society was held on Oct. [illegible], Dr. H. Radcliffe Crocker being in the chair.—Mr. Malcolm A. Morris showed two cases of Lupus Erythematosus in both of which the buccal cavity was affected. The first case was that of a man, aged 53 years, who had suffered from the disease more or less since he was 22 years of age. The present attack dated from about a year previously and was associated with severe abdominal pain, loss of smell, and numbness in the fingers but the sense of smell had returned. The tongue was red and raw-looking, there were lesions on the palate, and the cutaneous eruption affected the hands and the face. The second case was that of a woman, aged 30 years; the disease had started on the hand and then spread to the face and arms which were very severely affected. There were several small annular patches on the tongue showing a pale atrophic centre with red, congested margins.—Mr. Willmott H. Evans showed a boy with a Linear Mole affecting the area supplied by the dorsal branch of the left ulnar nerve on the back of the hand.—Dr. J. H. Sequeira showed a girl, aged 15 years, with a number of Ulcers and a Scar-leaving Eruption on both lower extremities. The eruption had started as blind boils in June, 1903.—The general opinion of those present was that it was a form of tuberculosis.—Dr. E. G. Graham Little showed: (1) A single woman, aged 45 years, who had suffered for 13 months with an Ulcerating Spreading Eruption on the Dorsum of the Right Foot and for a shorter time from a somewhat similar patch on the Left Thigh. That on the foot showed multiple steeply cut ulcers with very high tumour-like edges. There was no history of syphilis but this was the diagnosis generally offered.—Mr. Arthur Shillitoe showed a case of Gyrate Psoriasis in a man who had been also attacked with gonorrhœa. The case was shown to demonstrate the improvement which had taken place in the psoriasis from the administration of copaiba resin given for the gonorrhœa.—Dr. S. E. Dore showed a Russian suffering from Recklinghausen's Disease. The patient was covered with *café au lait* patches and small freckles and also exhibited numerous tumours beneath, and in, the true skin. One on the right forearm seemed to be connected with a nerve and this and one on the back were tender on pressure. The pigmentary changes had been present since birth, while the tumours were said to be still appearing.—Dr. A. Whitfield showed a man, aged 25 years, who had had syphilis five years before. 12 months previously a new outbreak of cutaneous gummata had appeared on the front of the neck leaving extensive scarring. At the same time some pustules had appeared on the back of the neck and had formed tumours. When shown there were two keloidal masses on the nape of the neck at the hairy margin and in these the hair follicles were gathered together by the contracting fibrous tissue so that the hairs issued in little brushes. The condition was a rare one and was known as acne keloid and generally believed to be unconnected with syphilis.

HUNTERIAN SOCIETY.—A meeting of this society was held on Oct. 14th, Dr. W. A. Dingle being in the chair.—The first Hunterian Lecture was delivered by Dr. W. Hale White, the subject being Some Clinical Considerations concerning certain of the Rarer Forms of Enlargement of the Heart. He first alluded to the difficulty of estimating by percussion whether the heart was enlarged and he then pointed out how much it might become hypertrophied as a result of pericarditis. This was due to the fact that the main function of the fibrous pericardium was to support the heart and to prevent its dilatation; hence when the pericardium was softened by inflammation the heart readily dilated and as when dilated it acted under a great mechanical disadvantage it soon underwent compensatory hypertrophy. The object of treatment must be to overcome the dilatation, because experience showed that when adhesions took place on the heart which was not dilated very little harm followed, but if the adhesions took place on the dilated organ the [illegible] his life from all the more [illegible] The treatment of pericarditis was discussed and also the best [illegible] Dr. Hale White next alluded [illegible] the specific fevers [illegible] which was due to [illegible] Four cases were narrated. In three of them a post-mortem examination was held and no other cause than alcoholic drink could be found for the enlargement. These three hearts weighed respectively 22, 20, and 20 ounces; no valvular disease or adherent pericardium could be found. The muscle was histologically healthy. The chief symptoms of the condition were dyspnœa and a rapid, feeble, and often irregular pulse; the cardiac impulse was displaced outwards and the sounds were faint; no murmurs were present. If the patient lived long enough severe dilatation might ensue and then there were all the symptoms of backward venous congestion. Owing to the presence of albuminuria such cases were difficult to distinguish from chronic interstitial nephritis. It was shown that such cases were especially common in those German towns where large quantities of beer were drunk. The cause of the condition was discussed and it was shown that nothing histologically abnormal could usually be found in the heart and that the condition could not be ascribed to any particular constituent of the beer, or to the quantity of the fluid drunk, or to alcoholic neuritis of the vagus. The last rare form of enlargement considered was that due to a fibroid heart and it was shown that this was a frequent cause of sudden death. Dr. Hale White mentioned that probably an alcoholic heart was commoner than was usually supposed.—A hearty vote of thanks was accorded to Dr. Hale White for his most interesting paper.

SOUTH-WEST LONDON MEDICAL SOCIETY.—The first meeting of the session of this society was held at Bolingbroke Hospital on Oct. 14th, Mr. E. F. White, the President, being in the chair.—Mr. P. J. Freyer read a paper entitled "Some Practical Remarks on the Enucleation of the Prostate." Having first referred to erroneous ideas regarding the anatomy of the prostate he described the prostate as consisting of [illegible] together to form a twin organ. [illegible] fœtal life the two lobes were [illegible] animals they were distinct throughout life. Each lobe was enveloped in a strong fibrous capsule and an outer capsule was formed by the recto-vesical fascia in which the large veins were imbedded. The ejaculatory ducts entered the prostatic urethra but did not pierce the capsule. Enlarged prostate was associated with a decline of sexual powers and assumed the form of an adenomatous outgrowth. As it grew it pushed the recto-vesical fascia before it. It could not advance in front owing to the triangular ligament. It advanced laterally until the levator ani and obturator were crushed against the sides of the pelvis. Then it grew into the bladder and gave the appearance of a middle lobe, but there was no middle lobe, only a prolongation of a lateral one. The main obstruction was caused by the lateral pressure of the two lobes, not as was generally supposed by the "middle" lobe acting as a ball valve. Mr. Freyer described the stages of the operation. Having performed a suprapubic cystotomy a finger of one hand was passed into the rectum and the prostate was pushed up into the bladder. The most prominent part was then attacked. The mucous membrane was scraped through with a sharpened finger-nail and the capsule was reached; this was tense and was not likely to tear. The organ was then enucleated with varying degrees of difficulty, but in the majority of cases it was easily peeled off. The cavity quickly contracted, similarly to the uterus after labour, and there was very little hæmorrhage. In no case had there been any contraction causing stricture and patients regained the power of retaining and passing urine without the aid of an instrument. Mr. Freyer showed a number of specimens which he had removed.

GLASGOW NORTHERN MEDICAL SOCIETY.—The first meeting of the session 1903–04 of this society was held on Oct. 13th, when the business reports of last session were read, [illegible] Campbell. Vice-Presidents: Mr. C. F. Spinks and Dr. J. Galbraith Connal. Treasurer: Dr. James Todd. Secretary: Dr. J. G. Gray. Reporting secretary: Dr. J. A. C. Macewen. Sealkeeper: Dr. J. C. Edmiston. Auditors: Mr. T. D. Waddell and Dr. John Ritchie. Ordinary members of the council: Dr. J. W. Allan, Dr. J. A. Wilson, Dr. J. B. Miller, Dr. J. Baird, Dr. M. Black, Dr. R. G. Inglis, Dr. W. Campbell, Dr. M. Campbell, Dr. J. Rutherford, Dr. Campbell S. Marshall, Dr. Muir, and Dr. J. Donald.

FOLKESTONE MEDICAL SOCIETY.—A meeting of this society was held on Oct. 9th, Dr. Thomas Eastes, the President, being in the chair.—The President read notes of a case of Division of the Ulnar Nerve and the Flexor Sublimis Tendons by a Piece of Glass. The nerve and tendons were sutured and all did well except that the final deep branch of the nerve was not known to be divided and escaped observation at the operation, so that the two distal joints of the little and ring finger were contracted.—The President also read notes of operations for relapsing appendicitis, chronic intestinal obstruction, hydatid cyst of the liver, and the radical cure of inguinal hernia; also of cases of ovariotomy, cholecystostomy, and myomectomy.

WIGAN MEDICAL SOCIETY.—An ordinary meeting of this society was held on Oct. 8th, the President, Dr. M. Benson, being in the chair.—Mr. C. M. Brady showed a Fibro-myomatous Uterus removed by Abdominal Hysterectomy.—The President opened a debate on Forceps in Midwifery with especial reference to Axis-traction Forceps.—An interesting discussion ensued in which the following members took part: Dr. F. Rees, Dr. J. Blair, Mr. M. G. McElligott, Mr. Brady, Mr. W. Mill, and Mr. W. Berry.—The President replied.

Reviews and Notices of Books.

Modern Materia Medica and Therapeutics. By A. A. STEVENS, A M., M.D. Pennsylvania. Third edition. London and Philadelphia: W. B. Saunders and Co. 1903. Pp. 663. Crown 8vo. Price 16*s*. net.

THIS work refers almost wholly to the drugs and preparations of the last United States Pharmacopœia which was published in 1893 In addition to these official medicines a few of recent introduction are mentioned but these are quite without references to authorities and the work in respect of comprehensiveness does not come up to our English Extra Pharmacopœia. The book is well bound in cloth and the print is large and clear but the volume seems to us unnecessarily heavy; if a book is to be a good deal in use it should be easy and light to handle. In this, the third edition, there is an entire rearrangement of the subject-matter and several of the chapters are quite new. The drugs are no longer in their alphabetical order but are classified according to their medicinal effects. The new arrangement seems satisfactory enough but there is but one general index for all parts of the book and to find any particular drug it is best to look for it under the name of one of the diseases for which it has been used as a remedy. Failing to find it there the reader may look for the drug under its own name and in case of non-success he is tempted to lay the book aside. As an instance of this, calcium chloride sought under the heading of chorea, or tuberculosis, or "scrofula," will not be found, though the drug has been widely used for the tuberculous glands of children. Under the heading of "calcii chloridum" it will not be found, though the drug is official in the United States Pharmacopœia. Under "hæmorrhage" the name will be found and on referring to p. 379 a short notice of the drug is given, no mention at all being made of its use in "scrofulous" affections of glands.

The part of the volume devoted to therapeutics only is on the whole satisfactory. There are excellent paragraphs on the sanatorium treatment of pulmonary tuberculosis. Among the directions as to how to deal with active hæmoptysis there is one with a quaint old-fashioned flavour about it. It seems to refer to the principle on which Junot's boot was used in the time of our grandfathers. "The application of firm ligatures to the limbs in order to lessen the volume of blood returning to the lungs" is what the author suggests as a practical method.

There is a good chapter dealing with remedial measures other than materia medica as the term is generally understood. Therein will be found notes on massage, medical electricity, the Schott treatment of chronic heart disease, the transfusion of blood and saline solution, phototherapy, blood-letting, and lavage of the stomach.

On the whole, Modern Materia Medica seems to be free from errors and a fairly readable book but we are a little doubtful whether it will become popular in this country.

A Manual of Practical Anatomy. By D. J. CUNNINGHAM, M D. Edin. and Dub., D.Sc. Dub., LL.D. Glasg., D.C.L. Oxon., F.R S., Professor of Anatomy at the University of Edinburgh. Vol. II.; Thorax, Head, and Neck. Third edition, illustrated with 222 Engravings, many in Colours. London and Edinburgh: Young J. Pentland. 1903. Pp. 607. Price 10*s*. 6*d*. net.

THE first volume of this new edition of Professor Cunningham's Manual has already been noticed in these pages. The second volume appears to be in every way equal in excellence to the first. It shows signs of careful revision and has been brought quite abreast of modern knowledge. The section which shows most change is that which deals with the positions and relations of the thoracic viscera. Here full advantage has been taken of the results of recent methods and investigations and the section affords an admirably lucid *précis* of present knowledge regarding the lungs, the pleuræ, the heart, the pericardium, and the mediastina. Very few of the old illustrations are to be found in this portion of the book, they having been replaced by an entirely new series. The remainder of the book is devoted to the dissection of the head and neck. Here we do not find any very striking alterations in the text but the new illustrations are a great improvement on those which they have replaced. An admirable feature of Professor Cunningham's book has always been the excellent description of the dissection of the brain. With the assistance of the artist this section has been rendered even more attractive than before. Throughout the whole volume the system of numerical references to the details of the illustrations has now been abolished and a system of guide lines and names has been substituted. By slight modifications in the type the size of the book has been reduced by a few pages in spite of the increased information contained. The book is very practical and by following the instructions given a student cannot fail to make the most of the part which he is dissecting. He should be warned, however, not to allow the manual to replace the use of a systematic text-book of larger size. The descriptions are so lucid and full that there is apparently a danger in this direction.

Die Wirkung einiger Bakterien und ihrer Toxine auf verschiedene Organe des Korpers. Arbeiten aus dem Pathologischen Institute zu Helsingfors (Finnland). Herausgegeben von Professor Dr. E. H. HOMÉN. (*The Action of Certain Bacteria and their Toxins on Different Organs of the Body. Research Work from the Pathological Institute at Helsingfors, Finland.* Edited by Professor E. H. HOMÉN). With 13 plates. 1902 Pp. 523. Price 30*s*.

IN this publication will be found an account of some important and interesting bacteriological work which has extended over a period of nearly eight years and has been carried out by Professor E. H. Homén and others at the Helsingfors Pathological Institute. In reviewing the work it will not be possible to do more than to indicate the nature of the researches and the conclusions that have been drawn from them.

Professor Homén has already published the results of his work on the action of streptococci and their toxins on the peripheral nerves, spinal ganglia and cord of rabbits, and he has now carried out similar researches with staphylococci, pneumococci, bacilli coli, bacilli typhosi, and their toxins. Cultures or their filtrated toxins were injected into the sciatic nerve of rabbits and also into the spinal cord. The animals were killed at varying intervals of time after injection and the nerves and the cords were examined microscopically. Professor Homén finds that the propagation of these bacteria takes place similarly to that of the streptococci *viâ* the lymph channels, especially along the inner side of the perineurium of the nerve and along the serous spaces and central canal of the cord, but that the extent and nature of this propagation vary somewhat for the different species of bacteria. Various inflammatory, destructive, and regenerative changes were found at the point of injection and in adjacent parts and these also vary for the different bacteria in nature, intensity, and extent, but we cannot go into further details on these points.

Dr. Ernst Ehrnrooth has carried out a series of experiments to determine how far trauma may act as a predisposing cause to changes in the brain which have been brought about by bacteria or their toxins injected into the bodies of rabbits. The main conclusions to which these experiments lead are that trauma predisposes the animal to infection of the brain or meninges by bacteria injected intravenously and that the degree, extent, and frequency of infection vary directly with the intensity of the trauma and inversely with the interval of time allowed to elapse between the trauma and the bacterial injection.

Dr. Max Björkstén contributes an article on his researches as to the action of certain bacteria and their toxins on the liver. Streptococci, staphylococci, pneumococci, and their toxins were injected into the bile-duct, directly into the substance of the liver, and also subcutaneously and intravenously, and the animals were either killed or died at varying intervals of time after injection and the liver was examined microscopically. This very thorough and extensive series of experiments shows that the bacteria in question are able to set up changes in the liver of a degenerative and necrotic nature which may terminate in a complete cirrhosis. Dr. Björkstén considers that the formation of fibrous tissue is secondary to the degeneration of the parenchymatous cells of the liver and that only later the presence of this new tissue formation causes atrophy of the liver cells. Dr. Björkstén also makes a preliminary communication on the action of staphylococci and their toxins on muscle tissue.

Dr. O. Streng gives a full description of his work on the action of certain bacteria and their toxins on the kidneys of rabbits and the separation of these organisms from the body through the kidneys. Pneumococci, staphylococci, bacilli coli, streptococci, bacilli typhosi, and bacilli prodigiosi were employed in these experiments and they were injected either into the large veins in the ear of the rabbit or subcutaneously. At varying intervals of time after the injection—from half an hour to 12 hours—the animals were killed and the kidneys and the urine in the bladder were immediately examined microscopically and by culture. The shortest time in which the bacteria appeared in the urine varied for the different organisms from half an hour for the bacillus coli to from six to eight hours for the staphylococcus and appeared to depend upon the rapidity with which the bacteria were able to set up inflammatory changes in the kidneys. Only at the end of longer intervals of time—from six to 12 hours after injection—when inflammatory changes with hæmorrhages were well established, did the bacteria appear in the urine in any quantity, so that Dr. Streng is led to the important conclusion that the passage of bacteria through the kidneys is dependent upon the changes previously set up in them by the organisms or their toxins and that bacteria are not excreted into the urine by normal healthy kidneys. His experiments with the filtrated toxins show that only exceptionally are they able to give rise to a parenchymatous nephritis. Dr. Streng also makes a preliminary communication on the cachexia caused by the injection of bacterial toxins into rabbits.

Dr. J. Silfvast has concluded a series of experiments on the action of staphylococci on the lungs and finds that intratracheal injections of the organisms into rabbits are able to set up a pneumonic process in the lungs. Inhalation of the cocci produced a similar result only when the animals inhaled fine particles of charcoal at the same time. A reduction of the temperature of the chest appeared to further the pneumonic process. Dr. Silfvast also concluded from his experiments that the lungs possess a considerable power of destroying the invading bacteria and that the phagocytes—the alveolar epithelium and leucocytes—play an important part in their destruction.

The authors have evidently conducted their researches with thoroughness and have set forth their results in a clear and concise manner

LIBRARY TABLE.

Tumours, Innocent and Malignant: their Clinical Characters and Appropriate Treatment. By J. BLAND-SUTTON, F.R.C.S. Eng., Surgeon to the Chelsea Hospital for Women, Assistant Surgeon to the Middlesex Hospital. Third edition, with 312 Engravings. London, Paris, New York, and Melbourne: Cassell and Co., Limited. 1903. Pp. 556. Price 21*s.*—This work well deserves the high reputation which it has attained. It deals with tumours in a fresh, unconventional manner and especially novel when it was first published was the abundant reference to the tumours occurring in the lower animals. In matters anatomical and physiological we have derived much valuable light from a study of the structure and mode of action of the organs of the lower animals, but the resemblances existing between the morbid processes in man and the rest of the animal kingdom had hardly been utilised at all until the appearance of the first edition of this book. It is true that John Hunter's researches into the region of animal pathology were numerous and important but much of his work was lost. Our knowledge of the etiology of tumours is very scanty and this applies alike to the innocent and malign growths, as the author points out; therefore this work does not devote to the discussion of this question space which can be more usefully employed otherwise; but, as we mentioned in reviewing the second edition, we should like to have his opinion on this difficult subject. The attention which Mr. Bland-Sutton has of recent years paid to gynæcological surgery is evidenced by the prominence given to new growths of the uterus and the ovaries, and we must acknowledge that he has thrown much light on an obscure subject. An important alteration in this edition is the separation of the myelomata from the sarcomata. They differ, indeed, in so many respects from the sarcomata that they deserve separate consideration but we think that there is an equal amount of reason for removing also the melanomata from the group of sarcomata. We are glad to see that the author has abandoned the name "epithelioma"; it has been used indefinitely of late years, for it has been applied to the columnar carcinomata as well as to the squamous variety and therefore it is far better to give up the word entirely. It is rather a pity to quote Kocher as having operated on 555 cases of "colloid struma"; the expression is sure to be misunderstood for the majority of the readers of the book will be unaware that "struma" in this place is merely the German for goitre.

Studies in Physiology, Anatomy, and Hygiene. By JAMES EDWARD PEABODY, A.M., Instructor in Biology in the Morris High School, New York City. New York: The Macmillan Company. London: Macmillan and Co. 1903. Pp. 332. Price 5*s.* net.—In the preparation of this volume the author has attempted to combine the following features. Emphasis is constantly laid on physiology, while anatomical details are given only so far as is necessary to make physiological processes intelligible Hygiene is discussed at the end of the study of each system. The simpler principles of chemistry are discussed in order that physiology may be understood. Physiological facts are considered from a comparative standpoint and the historical development of each is referred to. Scientific terminology has been avoided unless common names fail to give sufficient precision. Instruction is given regarding the effects of alcohol and narcotics and in this connexion extensive quotations have been made from the most recent report of the Committee of Fifty on the Physiological Aspects of the Liquor Problem. The book, which is intended as a manual of instruction for high schools and for the public, is very clearly written and the author has used every endeavour to secure freedom from errors. It is a very readable volume and the subject-matter is well arranged. The author's remarks on the care of the voice are well worthy of consideration. Colour-blindness is, however, irremediable, though a certain training in tints is, of course, practicable; from the remarks on this question at p. 307 a reader would suppose that colour-blindness could be corrected by training. The paper and print are excellent and the illustrations are for the most part good but the one of the human blood corpuscles (Fig. 43) cannot be included in this category. Some subjects appear to us to be treated with unnecessary minuteness considering that the book is intended for the non-medical public.

The Pedagogue at Play. By G. M. A. Hewett, Author of "The Open-Air Boy." London: George Allen. 1903. Pp. 296. Price 6*s.*—The author apologises in his preface for presenting for perusal so trifling a record of very ordinary doings. He has been tempted "to press in," first because he is always blundering up against the impression in the outer world that a schoolmaster is a sort of cross between an automatic machine and an iceberg and, secondly, because there seems to be very little record of the doings of ordinary men on ordinary holidays. These pages, however, require no apology for their production and certainly prove the first reason for their existence to be false. If any of our readers who are fond of sport and of descriptions of beautiful picturesque scenery dip into this volume they will find much to revel in. The English is good, the descriptions are breezy, the humour is ever-flowing, pure, and sparkling, and it is utterly devoid of morbid sentiment. The ten chapters mean delightful hours spent in the company of one who fully realises the art of enjoyment and who has tasted very fully of the pleasures of country life. Though many of the spots chosen have been sought out "in weariness of the everlasting presence of boy," we think that many a youngster, especially if he be a fisherman, will find much to satisfy him in Mr. Hewett's book, notwithstanding that the author does emphasise "the sort of joy that steals over the boy-ridden man when he finds himself for half a day turned loose on the grass with the harness off." In his chapter entitled "A Swiss Winter" he asks the question whether you want to renew your youth, whether you want to throw off 20, 30, or 40 years, whether you want to go through a spell of harmless but utter intoxication with no evil after-effects. There is but one answer to such a query and those of us who cannot know the joys of Grindelwald at its best may yet gain something worth having by following the author's glowing descriptions of places literally bubbling over with life and happiness. "The world is so busy, even over its pleasures, that it does a man good now and then to steep his soul in utter idleness amid such surroundings as these." We quote from the book and we know that to the busy practitioner hours spent in the perusal of this volume will pass as those of playtime. The author of "The Unspeakable Scot" should make the acquaintance of Mr. Hewett's "Mac."

Danish Self-Taught with Phonetic Pronunciation (Thimm's System). Edited by W. F. Harvey, M.A., formerly Universitetslektor at the University of Lund. London: E. Marlborough and Co. 1903. Pp. 120, crown 8vo. Price, wrapper 2*s.*, cloth 2*s.* 6*d.*—This manual, completing the Scandinavian group of languages in Marlborough's "Self-Taught" Series, is designed for the use of students and to meet the general requirements of tourists, merchants, commercial travellers, and other visitors to Denmark. The vocabularies are in three columns headed—"English," "Danish," and "Pronunciation." The idea of the phonetic or third column is to give in an intelligible manner the pronunciation at a glance of Danish as it is spoken among the educated classes at Copenhagen so far as words can possibly convey the exact sound. The system of phonetics is so simple that those previously unacquainted with Danish can with its aid make themselves understood without difficulty. The editor is an acknowledged authority on the Scandinavian languages and literature. Dr. A. Brahde of Copenhagen, a philologist of high repute, has revised the vocabularies and elementary grammar, while the phonetics have been composed under the superintendence of Mr. J. Thrige also of Copenhagen. The book is both practical and useful and will enable students and others to acquire the language by home study; the simplified grammar will also prepare the way for a more advanced course. With the small volume is bound up an extract from an article entitled "In the Queen's Country," which appeared in the *Christian World* and which tells of Denmark's picturesque scenery, its friendly people, and its historical and literary associations. We congratulate the publishers on the production of another of these useful serial volumes.

Die Sterblichkeit der Haupt- und Residenzstadt Budapest in den Jahren 1901–1905 und deren Ursachen. (*Mortality of Metropolitan and Residential Budapest in the years 1901–05 and its Causes.*) By Dr. Joseph V. Korosy. Second (tabular) volume, part 1, 1901. Berlin: Puttkammer und Mühlbrecht. 1902. Price one mark.—At first sight it seems strange that Dr. Körösy should have been able to state the death-rate for the years 1901–05, but probably that is the title which it is intended to put over the whole five years' work when it is finished. According to the results of the census of Jan. 1st, 1901, the population of Budapest amounted to 703,448 (exclusive of military 16,484). Of this number 339,649 were males and 363,799 were females. As regards age, the greatest number were between 20 and 30—viz., 160,392 persons—and 14 persons were over 100 years old. As regards religion, Roman Catholics numbered 427,112 and next in order came Jews with 166,198. 417 617 persons were unmarried, 238 256 persons were married, and 47,575 were widowers, widows, or divorcees. 562,237 persons each dwelt in from three to ten rooms. In March and January the greatest number of deaths were recorded (1386 and 1381 respectively), while in September and October the lowest numbers were recorded (961 and 976 respectively). The total deaths for the year were 13,923. The chief causes of death were: diseases of the organs of respiration, 4682; "morbi constitutionales," 2493; diseases of the nervous system, 1766; diseases of the organs of digestion, 1537; infectious diseases, 1130; and diseases of the circulatory system, 1084. The list of diseases is printed in Hungarian and Latin and the remainder of the report is printed in Hungarian and German. Incidentally it affords a useful dictionary for those interested in the study of languages.

The Story of my Life, by Helen Keller, with her Letters (1887–1901) and a Supplementary Account of her Education by John Albert Macy. London: Hodder and Stoughton. 1903. Pp. 441. Price 7*s.* 6*d.*—This is the autobiography of a most extraordinary woman—of a young lady who, although totally blind and deaf, has learned by the sense of touch to communicate with friends, to read, to write on the typewriter, and to speak French and German as well as English—in fact, of one who has broken down the barrier between herself and the outside world. The work has created some sensation in the United States and is one of the most remarkable records of the triumph of human endeavour over physical affliction. Mark Twain has said that "the two most interesting characters of the nineteenth century are Napoleon and Helen Keller." The book is in three parts. The first two, Miss Keller's story and the extracts from her letters, form a complete account of her life so far as she can give it. For the third part the editor is responsible, and in writing it he has had the advantage of the advice of Miss Sullivan—Miss Keller's friend and teacher; it is a further account of her personality and achievements. The book is a beautiful record clothed in expressive language of the wonderful perseverance of a pure-minded human being—a record of how one terribly afflicted has conquered and passed from darkness into light, from isolation to friendship, companionship, knowledge, and love. It is the story of one who has heard a voice which said, "Knowledge is love and light and vision," who is in love with noble things, with noble thoughts, and with the characters of noble men and women.

THE LANCET.

LONDON: SATURDAY, OCTOBER 24, 1903.

The Huxley Memorial Lecture.

THE subject selected by Professor KARL PEARSON for the Huxley Memorial Lecture is one which must appeal to the interest of all classes of society and his conclusions will be endorsed by all medical men who work much among the poorer classes. The title of his lecture was the Inheritance in Man of Moral and Mental Characters and its Relation to the Inheritance of Physical Characters, but his conclusions from careful inquiry suggest that a less cumbrous title would have been more attractive and equally appropriate, since they turn on the relative national advantages of education and of physical training with improved hygienic conditions. For the last six or seven years he has been collecting information in three directions—namely, first, an inquiry into the actual values of inheritance of the physical characters in man; secondly, a comparison of the inheritance of the physical characters in man with that of the physical characters in other forms of life; and, thirdly, an inquiry into the inheritance of the mental and moral characters in man It is not necessary to reproduce the statistics upon which he has worked, since arrays of figures, though instructive, are often repellent. In the present instance they serve to demonstrate the truth of a contention often advanced in these columns—viz, the danger to the community of excessive attention to education, with comparative neglect of the general physique. Professor PEARSON is emphatic in his statement that no scheme of wider or more thorough education would bring hereditary weakness up to the level of hereditary strength in the scale of intelligence. This is another way of stating that we are what our forefathers have made us, that there is a certain hopelessness in trying to work upon raw material if the raw material is of poor fibre. In our public schools this elementary fact has long been recognised and acted upon, but the question is more widespread, since only a very small proportion of the community can enjoy the advantages calculated to produce a sound mind in a sound body. Clearly, however, from the statistics before us these two must be more widely conjoined to prevent mental and moral decadence in any race.

This, indeed, leads to the most difficult problem of sociology, since it involves an interference with the present freedom from control. Professor PEARSON maintains, although he admits the difficulties in the way, that the only remedy is to alter the relative fertility of the good and bad stocks in the community. The children who inherit poor mental, moral, and physical characters are apparently numerically outweighing those of superior powers and the result is a rapid levelling down which defies all efforts at improvement by education. Every practitioner is familiar with the large families living in cramped insanitary surroundings on poor wages; the poor man in adversity generally has numerous olive branches struggling for existence and handicapped from the outset by insufficient food and by overcrowding. The craft of forestry suggests thinning and weeding out to prevent stunted undergrowth from hindering healthy development and in SWIFT'S "Modest Proposal" a sufficiently savage method of weeding was suggested; but human beings cannot be treated like superfluous trees or kittens and the alterations of relative fertility in different classes of society must be antenatal The prevention of improvident marriages might do some good but it would be a bold Ministry which would venture to introduce an Act of Parliament to render matrimony dependent upon any fixed weekly wage. Still, many of the employés of banks and city firms have to submit to a regulation which discountenances early marriages on insufficient means.

Professor PEARSON looks, however, to the upper rather than to the lower classes in fixing the responsibility for decadence. It is not so much the increase in the fertility of the latter as the diminished fertility of the former which tends to reduce the mental, moral, and physical standard. He states that for the last 40 years the intellectual classes of the nation, enervated by wealth or by love of pleasure, or by following an erroneous standard of life, have ceased to give us in due proportion the men wanted to carry on the ever-growing work of our empire, to battle in the fore rank of the ever-intensified struggle of nations. Can medical men in the ordinary course of their work do anything towards the solution of the difficulty? We venture to think that the influence of the medical profession is continually being exerted in directions which would meet with Professor PEARSON'S approval. For instance, advice on the subject of matrimony on the score of physical weakness, inherited or acquired, is frequently sought and indeed forms one of the most painful duties of a profession overburdened with responsibility. With the other side of the question, however—the encouragement of those who with advantage to the State might and should marry but do not—we have little to do. Indeed, the subject of the Huxley Memorial Lecture, though fascinating, can only in part be dealt with by the medical profession; it really can only be approached by modern statecraft. But there is one obvious conclusion to be drawn—viz, the need of greater expenditure on hygiene and physical training than upon mere education. It is to be hoped that the committee appointed to consider certain aspects of the alleged physical deterioration of the people will not lose sight of the importance of its bearing upon the mental and moral characters which must so largely influence national welfare.

◆

The Vintage and its Relationship to Health.

THE question as to whether a vintage is or is not a success is of some importance to the public health. The terms used by the wine-grower to describe a vintage such as "a stout and full-coloured vintage," "a beautiful clean vintage," "fine quality distinguished by body rather than elegance," and "very thin and inferior," if colloquial are expressive and often contain within them a meaning of hygienic significance. The success of a vintage is a matter for congratulation, not merely because it spells prosperity to the viticulturist and all who are industrially concerned, but because also it means that when plenty and quality are the rule a good, sound, and wholesome wine will be the result, while necessarily a rich, abundant harvest is calculated to reduce the opportunities of the adulterator. On the other hand, when the vintage fails, or partly fails, or the yield is small and the fruit is immature or perhaps attacked with disease, temptations may arise to adopt devices by which the wine may be made marketable. It is a pretty fair conclusion to draw, we think, that bad or inferior fruit will make bad wine or that fruit attacked by oidium or other disease will yield a more or less unsound product. This much importance, therefore, is to be attached to a vintage, that according to whether it is a success or a failure so will its influence be calculated to be for good or for bad upon the health of the wine-consuming public. There is yet another hygienic aspect of the quality of the vintage. In the years of abundance, when there is plenty of sun to ripen the grape and to produce much rich juice, the wines are generous in character, they are full, more invigorating, and contain more "vinosity" and alcohol than the wines of wet, sunless years, and such rich wines should, of course, be consumed in comparatively sparing quantities or, better still, be put aside until the remarkably softening and ripening influences of time are brought to bear upon them. The wines produced in our colonies, which are invariably richer and stronger than those produced in France or Germany, would lose much of the crude qualities which are characteristic of them were they left to mature. While these wines, be it said, have many excellent points they cannot at present compete as regards delicacy or *finesse* with the more classic wines of French growth. But the vintages of our colonies, owing to the steadier condition of climate and to an abundance of sun, are, as a rule, more certain and more regular than the French or German vintages and thus the wines of Australia are constant in character, always full, and always generous. Of a similar character are the wines of California Spain, Algiers, Greece, Turkey, and Persia. There is an undoubted future for our colonial wines and some day not far distant it is to be hoped that they may appeal to the connoisseur's taste more than they do now and be of a more refined character. Colonial wines at the present time are very popular, partly because they are cheap and partly because of their "vigorous" character. It has been said that the day of glorious vintages in regard to French wines has passed and that never again shall we see such exquisite wines as were produced in the Médoc, for example, in 1864, 1865, 1874, 1875, or even 1888 or 1889. We do not believe it. It is confidently to be hoped that the wretched weather which has prevailed in this country during this year, and in many of the finest wine-growing countries, may prove exceptional and that seasons of sunshine (than which no other agent is more essential to the health and the life of the grape) as well as those other beneficent meteorological conditions which marked the years of famous vintages will again contribute towards making the vineyards as productive as ever of wines of refinement and quality. In spite of indifferent seasons, however, ordinary table claret when procured through respectable channels has never been so good, so plentiful, and so cheap.

According to the latest accounts it is to be feared that the prospects of the present vintage which is just being gathered are somewhat cheerless and unpromising. The yield in general will be small and the year 1903 will not figure in the coming records of vintages as a year of much brilliance. White wines are a conspicuous failure, although some small success is promised in regard to the famous sparkling wines produced in the neighbourhood of Reims, owing to the spell of fine weather in September. Long-continued rains have damaged the vines of the Bordeaux districts and the crop is small. From Beaune comes a similar story, while the news from Jerez de la Frontera, where the heat has been intense and the season dry, is in favour of a fairly good vintage. Again, port will not rank high either in quality or quantity this year and the yield of wine along the banks of the Rhine and the Moselle is small and the wine is without any great promise of fine development. The harvest in the Charente is also small, owing to which circumstance probably much of the wine is being bought for direct consumption and will not reach the still at all; the yield of brandy, therefore, is likely to be small. Against all this we have the report that the vintages of South Australia and California are satisfactory as regards both quality and quantity.

The choice of a wine is a matter so frequently referred to the medical man by his patient that it may be well to recapitulate some of the facts about the composition and character of various wines as disclosed from time to time in our analytical columns. The soundness of a wine may be largely judged from its degree of acidity, which is commonly higher in white wines than in red wines. Moreover, as we have frequently pointed out, white wines as a rule contain decidedly more sugar than do clarets, although frequently a white wine is ordered because the reverse is supposed to be the case. Claret would appear to have, therefore, certain advantages over white wines for those suffering from diabetes or gout. A good, sound claret seldom contains more than 0·20 per cent. of sugar, 0·10 per cent. of acetic acid, and 0·20 per cent. of free tartaric acid, while sauternes, for example, frequently contain from 1·5 to 3 per cent. of sugar, about 0·10 per cent. of acetic acid, and from 0·30 to 0 50 per cent. of tartaric acid. A sound burgundy again contains rather more sugar than does claret, the amount of the acetic acid is about the same as that in claret, but the amount of tartaric acid is higher. Champagne ordinarily described as "extra dry" contains from 1½ to 3 per cent. of sugar, while a "brut" champagne—i.e., an unliqueured wine—contains about the same amount of sugar as does sound claret. The percentage of tartaric acid in champagne is decidedly high. Champagne, in fact, is rich in the salts of the grape which resolve into alkaline carbonates in the body. Many persons experience a sense of thirst after drinking champagne, probably for this reason. The ethers in champagne, with the exception perhaps of old sherry, exceed in amount those in most white wines, a fact, coupled with its effervescent qualities, which makes it a rapidly diffusible stimulant and a sense of well-being is experienced much sooner after drinking champagne than is the case with most other wines. The wines of the Saumur district have improved very much of late; they closely resemble champagne but are lighter in character. As regards the dietetic suitability of red wines more attention, it seems to us, might be paid to their astringency which depends upon the tannin-like substances derived from the grape skin. It cannot be supposed, however, that red wines have a very marked tendency to produce constipation, for the presence of tartrates probably prevents any effect of this kind which might otherwise ensue. Red wines, and especially those of the burgundy type, have been observed to produce some blackening of the fæces, which may be due to the iron of the colouring matter of the grape skin, although it is conceivable that tannin might produce a similar effect and the amount of iron in red wines is according to our experience insignificant. White wines, including, however, champagne, contain relatively little tannin and tend to an aperient effect whilst causing little or no change of colour in the dejecta.

Though it may be doubtful whether in the wines of the same vintage and district any important differences in regard to their chemical composition exist, it is nearly certain that such important dietetic constituents as the alcohol, the sugar, the total acids, the ethereal bodies, the astringent principles, and the salts would vary in quantity according to whether the vintage could be described as good, bad, or indifferent. And since the quality of the wine is thus decided it follows that some hygienic importance, as we have said, attaches to the character of the vintage.

◆

Toxins and Antitoxins.

THEORIES are the weapons of master-minds for the attack of scientific problems but with men of lesser calibre the theory is apt to become the master instead of the servant. The theory of immunity propounded by EHRLICH has been in his hands and also in those of most of his followers used only as a working hypothesis suggesting lines of research which have yielded results of the highest importance. Still, it is well that we should beware lest the theory distort our view of the facts and that we should be reminded, as by the critical paper by Dr. E. F. BASHFORD in THE LANCET of Oct. 17th, p. 1076, that the observed facts may possibly have another interpretation than that usually given. At the same time it is to be noted that Dr. BASHFORD is careful to explain that his criticism does not invalidate the routine prevalent methods for the standardisation and testing of antitoxic sera. EHRLICH'S theory of immunity, which formed the subject of the Croonian Lecture delivered before the Royal Society in 1900, has since been brought prominently before the medical profession in at least two series of lectures—in the Huxley Lecture by Professor W. H. WELCH and by Dr. A. S. F. GRÜNBAUM in the Goulstonian Lectures. It has certainly been fortunate in its exponents. If there be any lingering obscurity it is probably due, apart from the inherent difficulty of the subject, to two main causes. The first is the extremely technical language in which, almost of necessity, it has become involved; and the second is that the theory covers much more than that form of immunity due to the presence of antitoxic bodies with which it has been especially connected in the minds of practical physicians.

It has been well said in a recent work[1] that "the factors involved in securing immunity against infectious diseases are multiple in number and varied in character." Apart from those forms of immunity which rest on general causes such as the difficulty an organism finds in entering the body or the unsuitability of the channel by which it gains access, specific immunity to bacterial disease may, viewed broadly, be said to rest either upon the neutralisation of the poison by which an organism produces its pathogenic effect or upon the destruction of the micro-organism which has gained access to a susceptible host; this destruction may be due directly to cellular activity or indirectly to the action of bactericidal or lysogenetic substances. A valid theory of immunity should, of course, take into consideration all the factors which bring about that condition, and it is the great beauty of EHRLICH'S explanation that it connects by one common bond natural with artificial immunity and the various forms of artificial immunity, whether produced by antitoxins or by bactericidal bodies. Further, it does not invoke any abnormal forms of metabolism but refers the production of these various protective bodies to variations in the normal processes of cell nutrition. Necessary as it is for theoretical reasons to regard the various forms of immunity as a whole we may for practical purposes regard them separately, and indeed this separation is requisite when we deal with the facts as opposed to the theories of immunity. Fortunately, these facts relating to antitoxic bodies are comparatively simple and clear. In a very limited number of bacterial diseases practically all the symptoms of the disease can be produced by toxic bodies found in the filtered cultures of the specific microbe. By the repeated injection of these toxins in non-lethal doses susceptible animals may be rendered immune so as to be unaffected by many multiples of the original fatal dose. In the blood serum of these immunised animals a body is found which is capable of neutralising in vitro or in the animal body the toxin employed in the process of immunisation, so that a mixture of the blood serum and the toxin in certain proportions is no longer capable of producing pathogenic results. This neutralising body is antitoxin and neither it nor the toxin has been isolated: they are recognised only by their physiological properties. Such antitoxins are known in the case of tetanus and diphtheria, in a less definite manner in plague, and possibly, according to the recent work of Dr. A. MACFADYEN, they may be present in typhoid fever. Similar bodies are found in the blood serum of animals immunised against snake venom and the vegetable poisons abrin and ricin. In this very limited class of diseases or intoxications acquired immunity primarily depends on the presence of the neutralising antitoxin. It will be noted that this antitoxic material appears as the result of the injection of the corresponding toxin or may be transferred, as in the injection of antidiphtheria serum, from one animal to another. These facts do not furnish any ground for a general theory of immunity, as even in the diseases mentioned animals naturally immune need not possess any antitoxic body in their blood.

---

[1] Vaughan and Novy: Cellular Toxins.

The relation between toxin and antitoxin, at one time regarded as a physiological one, is now considered to be of the nature of a chemical reaction similar to that which exists between an acid and an alkali. Of course, as our test for neutralisation is physiological and not chemical, as is pointed out by Dr. Bashford, there is room for a large margin of error, nor, since we are unaware that there is any phenomenon corresponding to precipitation in this interaction, *can we expect the influence of mass to be absent* in this any more than in other chemical changes. It is, however, possible to fix the neutralising relationship between toxin and antitoxin with sufficient accuracy to satisfy the requirements of practical medicine. It is difficult to believe that such intimate union as is implied by the effects produced by a toxin on the susceptible tissue should be of other than a chemical nature, and it is found experimentally that all toxins capable of giving rise to antitoxic bodies are so intimately combined with the cells that they cannot be separated by other than chemical means. Ehrlich's explanation of these facts is that a toxin poisons a cell by uniting chemically with an unsatisfied affinity—a side chain—of some cell constituent which is required to carry on the ordinary metabolism of healthy cell life. The cells thus poisoned, and possibly also similar associated cells, if in process of recovery reproduce this side chain of the cell constituent with its potential toxin-combining affinity, so that once more the cell can carry on its normal processes. Under the constant stimulus of the toxin, as occurs in the process of immunisation, these toxin-combining side chains are not only reproduced but developed in excess of the cell requirements and are then cast off into the general circulation. These side chains, produced in excess, capable *ex hypothesi* of combining with the toxin and existing free in the circulation, constitute the antitoxin. There are many facts which go to show that antitoxin is the product of cell activity under the influence of a stimulus, generally that of the corresponding toxin, but in some cases that of non-toxic derivatives of the toxin, and the yield of antitoxin in an immunised animal may be increased by the injection of such a cell stimulant as pilocarpin. The widely extended use of antitoxin in the treatment of diphtheria makes these neutralising bodies bulk large in our conceptions of the means by which immunity is produced, but it is in but a very limited number of diseases that antitoxins can be shown to exist The production and therapeutic use of antitoxic sera are, of course, based on solid experimental grounds. The means by which the relations between toxin and antitoxin are gauged have also an experimental basis, though theoretical *reasonings have led to the development of the present* practical methods.

Annotations.

"Ne quid nimis."

EPSOM COLLEGE.

We are sure that many of our readers will be glad to hear that the council of the Royal Medical Benevolent College of Epsom has decided to take the necessary legal steps for the purpose of changing the official title of the institution to "Epsom College." It will be seen on reference to our advertising columns that an extraordinary general meeting of the governors is to be held on Wednesday, Nov. 11th, for the purpose of making the requisite alteration, since the amending Act of Parliament obtained in 1894 provides that the passing of a motion at a general meeting to the effect that the name of the College is to be altered will be all that is required to effect the legal change of title. Those qualified to judge have for many years believed that two words in the long title have militated against the success of the educational side of the institution. "Medical" certainly conveys the idea that the College is a "class" school and almost all persons nowadays grant that schools for the children of members of a single profession are undesirable; and the term "Benevolent" serves to stamp all scholars as being in receipt of an education more or less of an eleemosynary character. As Epsom College contains a very large number of pupils who pay full fees, many who are not sons of medical men paying as much as 75 guineas a year, the word "Benevolent" applied to the school as a whole is certainly misleading. The Lancet was probably the first to take exception to this word, for in the year 1851, when the late Mr. Propert inaugurated this noble work, the following appeared in our columns: "We wish then the proposal of Mr. Propert good speed. We should like to see the term 'benevolent' omitted from the title, but for the objects of the institution, whether for eleemosynary or educational purposes, we have but one word and one thought—that of hearty coöperation and support." Soon after this a rumour was circulated that it was proposed to make the College a class school, and as a consequence we wrote in a leading article on Nov 29th, 1851, as follows: "It has gone abroad as an objection to the scheme that the school will not only be exclusively for the sons of medical men but for those sons only who are intended for the profession. The idea is monstrous. We have authority for stating that the school will not be confined to the sons of medical men, but the foundation will be exclusively for the orphans and sons of distressed members of our own profession, whatever be their future destination." The advertisement shows that in proposing to change the title the council is not unmindful of the importance of the charitable side of the institution—namely, the giving of pensions to 50 aged medical men or to their widows and the provision of board, education, and clothing free of charge for 50 foundation scholars the sons of medical men in distressed circumstances. It is proposed to pass a standing order of the council directing that in documents issued from the office in London the following words shall appear immediately after the title: "Established in 1855 as a public school with a Royal Medical Benevolent Foundation." The idea appears to be a happy one, for it not only traces the institution under its new title of Epsom College back to its foundation close upon 50 years ago, so that friends of the old title may easily recognise it under the new one, but emphasis is laid upon the fact that a great medical charity is combined with a public school. This fact was never clear under the old, misleading title of "Royal Medical Benevolent College," since the granting of pensions cannot by any stretch of the imagination be associated with a *college*. There is one other side to the question and it would have held good even if the College had contained only foundation scholars: it is not true charity constantly to remind those who, owing to adverse circumstances, have been compelled to receive a gratuitous education that they have been to a benevolent school.

KING EDWARD VII. SANATORIUM.

ANOTHER stage will be reached in the progress towards the realisation of the King Edward VII. Sanatorium for Tuberculosis on Nov. 3rd when the foundation stone will be laid by His Majesty the King at Lord's Common, Easebourne, Midhurst, Sussex. The advertisement for the best essays and plans appeared in THE LANCET of Jan. 4th, 1902, between pages 36 and 37 and the name of the donor of the £200,000 for the sanatorium, Sir Ernest Cassel, K.C.M G., was announced in our columns on Jan. 11th, 1902, p. 111. The result of the prize competition for the best essays and plans was given by us on August 9th, 1902, p. 369, and the three prize essays and plans were published in THE LANCET of Jan. 3rd, 1903. In our issue of May 16th, 1903, p. 1391, we stated that the site chosen had been acquired from Lord Egmont at Lord's Common, Easebourne, six miles south of Haslemere and about three from Midhurst, and that it was 150 acres in extent. Midhurst is about 64 miles from Waterloo station (L. & S.W.R.) and the time occupied by the journey is from two and a half to three hours.

THE DEATH OF MISS HICKMAN.

THE body of Miss Hickman was found on the afternoon of Sunday, Oct. 18th, in one of the inclosed plantations of Richmond Park in a condition which leaves no doubt that it had lain there during the whole, or almost the whole, of the period which has elapsed since her disappearance from the Royal Free Hospital on August 15th. The inquest which is being held upon the remains will submit to the test of open inquiry and cross-examination such information as may be available as to the last occasions upon which the deceased lady was seen alive and to a considerable extent, if not in every detail, should elucidate the mystery of her fate. The mere discovery of her body in such circumstances has served to dispel the more distressing and alarming of the theories which have been suggested and circulated. To some extent also an explanation may be afforded before the coroner of the fact that in a public park and pleasure resort within eight miles of the centre of London the dead body of a person of whose disappearance everyone is aware may lie, practically unconcealed, for more than two months. It is true that the public are excluded by the regulations of the park from the wood or plantation in question and that owing to the preservation of game some care is no doubt exercised to enforce the rules laid down. It was not, however, in any way physically inaccessible and, as a matter of fact, the small boys who made so grim a discovery while looking for horse chestnuts had no difficulty in entering or leaving it. That Miss Hickman had been seen in the park was one of the most tangible of the many rumours regarding her movements after leaving Gray's Inn-road and the past residence of her family in the neighbourhood gave a certain colour of probability to the story. The fact, however, remains that neither police nor parkkeepers, either in the exercise of their ordinary duties or in consequence of the suggestions put forward, made a discovery which would have spared a long period of anxiety to those upon whom the terrible period of suspense and the complete absence of information have weighed most heavily. The matter may tend to prove the limitations to which investigation is necessarily subjected upon such occasions rather than to show that want of care or intelligence can be attributed to those concerned; the fact, however, of the presence of a corpse having so long remained undiscovered in such a place will remain as one of the conspicuous features of a tragedy which has aroused the sympathy and wonder of the whole country. To the bereaved relatives and friends of Miss Hickman we tender our respectful condolence in their sorrow which has now lost the element of suspense together with whatever faint hope may have hitherto survived. At the inquest which was opened on Oct. 21st before Mr. M. H. Taylor, coroner for Mid-Surrey, medical evidence was given by Dr. M. H. Gardiner and by Mr. A. J. Pepper that no signs of death from violence were found at the post-mortem examination. The result of the examination as regards the cause of death was entirely negative. The inquiry was adjourned to Nov. 5th.

THE HATCHING OF CHICKENS FROM PRESERVED EGGS.

IN a letter from a correspondent published in our present issue attention is again called to the remarkable preservative effects on eggs of silicate of soda Some months ago[1] we referred to a statement which had been made that a chicken had been hatched from an egg which had then been preserved for 12 months. Our correspondent endeavoured to hatch eggs which had been preserved for three months. This he entirely failed to do but he found that the eggs, even when they had been incubated for over three weeks, remained perfectly fresh and could not be distinguished from recently laid eggs. He points out that if the preservative effect of the silicate of soda is due to the formation of an impermeable substance in the shell of the egg—and there seems no reason to doubt this explanation—then it can hardly be expected that the chick will develop unless some method is adopted in order again to render the shell permeable to air. Experiments in this direction would be of great interest.

MORAL DELINQUENCY IN CHILDREN.

IN an annotation which was published in THE LANCET of July 18th last (p 175) reference was made to the observations and cases recently reported by Dr. A. McLane Hamilton concerning insanity and moral delinquency in children. In the *Daily Express* of Sept. 25th an account was given of a little girl who was the subject of murderous tendencies of a peculiar sort. The child is described as "a bright-eyed girl of nine, innocent looking, with a happy smiling face," who had a propensity for luring little boys to a brook and throwing them in and leaving them to drown. Twice during the week preceding her trial she had sought to carry her murderous instincts into effect. Some time previously she lured a boy six years old and pushed him into a stream but after watching his struggles for some moments she helped him out again. For this deed she was kept in close confinement for ten days and almost her first act on regaining her freedom was to entice a little boy aged three years to a brook, to throw him in, and to run away By the merest chance the incident was witnessed by a man who was working near and the little one was rescued. She had attempted to drown another child in the same way. A curious absence of the sense of remorse was exhibited by this youthful criminal. Questioned by the magistrate she is said cheerfully to have admitted that she threw children into the stream but she could not say what prompted her to do it. Apparently, all motive was lacking except the innate instinct of murder. That the child was mentally abnormal was shown by the evidence of her mother. "From a very early age she had been a source of endless trouble to her—disobedient, wilful and mysterious in her ways, and developing instincts of the most amazing character." On the magistrate making the order that she should be sent to an industrial school, where she was to remain till she was 16 years of age, she manifested no concern. Her composure was not disturbed in the least, so the report states, by the strange surroundings of the court, the presence of policemen, the recital of her misdeeds, or the prospect of a seven years' exile from home and from her mother, and when she was taken away in the charge of a constable she looked quite innocent. Her intelligence is said to be somewhat dull but she exhibits none of the characteristics of ordinary insanity—mental excitement or depression, incoherence, delusions, hallucinations, or stupor. Possibly, a long sojourn in a reformatory, prolonged education and moral training, the influence of religion, and the teaching of some useful handicraft might contribute towards the amelioration of such a case. The advent of puberty may, however, be marked with recurrence or disappearance of bad symptoms.

---

NEW ENTRIES AT THE MEDICAL SCHOOLS.

WE have not as yet received from all the medical schools of London and the provinces complete returns of the number of students who have entered their names for a full course of medical study during the year 1903-04 and we cannot therefore judge with certainty as to the increase or decrease in numbers. From the figures already to hand, however, London will probably show a slight increase, while the provinces may show a decrease. In London the most notable increase is at St. Mary's Hospital Medical School, where the figures are 42 as against 26 for the session 1902-03. St. Thomas's Hospital Medical School had 42 new entries last year and has 48 this year. The London School of Medicine for Women, which has 36 new entries this year, had 28 last year. One of the dental hospitals of London shows an increase, while another shows a falling off. In the provinces, so far as the figures that we have already received show, there has been a falling off all round with the exception of the Owens College, where the new entries were 48last year and are 51 this year, an increase of 3. We hope to be able to publish a complete table next week.

THE CARE OF PAUPER CHILDREN.

ONE of the most serious matters with which the Poor-law concerns itself is the problem of preventing the children of paupers from following in the footsteps of their parents and the last few weeks have been more than usually prolific in discussion of this vital question. Much has been said for and against the various systems of dealing with the needs of the children and while there is now practically universal agreement that the workhouse atmosphere is ill suited to the development of a sound mind in a sound body there is no uniformity of opinion as regards the selection of a substitute. Schools, scattered homes, collected homes, "boarding out"—each of these has its enthusiastic supporters armed with abundant evidence in favour of the cause. Some time ago we had occasion to notice with approval the Poor-law Schools Exhibition held in the Church Hall at Westminster and we observe that the children who then displayed their capabilities as gymnasts have again been supplying, at swimming competitions held in the Westminster baths, proof of their physical fitness. What has been called the "Sheffield system"—that of scattered homes—was reported on at the North Midland Poor-law conference by the clerk to the Sheffield union who assured his auditors that they might be certain of one thing at least—namely, that the children who passed through the homes did not return to the workhouse. At Plymouth, too, homes of this class seem to have been found to be satisfactory. That there is also something to be said for a colony of cottage homes is evidently believed by the Ecclesall Bierlow guardians for whom the foundation stone of a collection of buildings of this class was recently laid at Bole-hill Lane near Sheffield. The Right Hon. W. H. Long, the President of the Local Government Board, who assisted at the proceedings, took the opportunity of explaining his own position in regard to these different methods. He was, he said, constantly being pressed to lay down a hard and-fast rule as to the measures which guardians should take in connexion with what he described as "this the most important question of Poor-law administration." He had refused to accede to such a request for two reasons, the first of which was that he had never been able to satisfy himself sufficiently that one system was superior to the rest and the second was the confidence he felt in the ability of guardians as a whole to turn their local knowledge to account in deciding which method was best adapted to the special needs of their district.

INTESTINAL ANASTOMOSIS.

ANY difficulty which a surgeon may experience in performing intestinal anastomosis can in no way be attributed to any lack of methods of carrying out this operation presented to his choice. Up to the present some 250 varieties of modes of uniting two pieces of bowel have been described but we should hardly like to assert that they have all been carried out on the living patient, for probably many of them have never been employed in practice. They range in complexity from the simple suture to the ingenious forceps of Laplace and include an immense number of mechanical appliances. There are still many advocates of simple suture—in fact, we consider that we should be justified in saying that this method is used by the majority of surgeons. The essentials of a good method of intestinal anastomosis are that it should be, in the first place, trustworthy and, in the second place, easily and rapidly applied. Both of these conditions are fulfilled by the simple suture. If carefully performed no other method surpasses it in security and with a little practice the application of the stitches does not take much more time than many of the methods especially designed for speed. Moreover, the requirements are obtainable everywhere; if necessary an ordinary sewing needle and cotton can be readily sterilised and employed. In spite of the claims of the simple suture there has been a constant endeavour to obtain some method which can be more rapidly applied. Maunsell's method was ingenious but it inflicted an additional wound on the bowel and it is now, we believe, but little used. In most of the other methods some mechanical arrangement is employed to facilitate the junction of the two portions of bowel and of these Murphy's button is the best known. It is capable of uniting very satisfactorily two portions of bowel and it can be very rapidly applied after a little practice. There is to Murphy's button a very great objection. A foreign body—the button—is left in the bowel and it may be retained there for many weeks or months and though its downward progress may be watched from day to day by means of the x rays and a fluorescent screen, yet its retention for a lengthy period cannot but cause anxiety to the surgeon. To eliminate this difficulty of a foreign body and yet to retain the convenience of a mechanical support various absorbable devices have been tried. We believe that Mr. A. W. Mayo Robson's decalcified bone bobbin was the earliest of these and various modifications of it have been introduced. The latest of these has been invented by Dr. A. MacLennan of Glasgow, who a few years ago devised two other methods. His present invention is certainly ingenious and from *a priori* considerations we should expect it to prove successful. It is a grooved bone bobbin and by means of ligatures the peritoneal surfaces of the two portions of bowel are kept in contact on it. Various sizes of bobbin are made so that one suitable for any particular case may be employed. Judging from the description we should think the process would be simple and speedy but whether it will supersede the simple suture remains to be seen. For the full account of the bobbin we refer the reader to the article published at p. 1156 of our present issue.

WORKHOUSE NURSING AND THE PROPOSED "QUALIFIED NURSE."

AT a meeting of the Hospitals Association which will be held in the Governors' Hall, St. Thomas's Hospital, Albert Embankment, S.E., on Thursday, Oct. 29th, at 4.30 P.M., a discussion on the report of the departmental committee on nursing appointed by the President of the Local Government Board will be opened by Miss Gibson, matron of Birmingham Infirmary, and Dr. T. D. Savill, formerly medical superintendent of Paddington Infirmary. Tickets of admission may be had on application to Mr. Sydney Phillips at St. Thomas's Hospital.

PLACENTAL TISSUE AS A GALACTAGOGUE.

IN THE LANCET of Oct. 3rd, p. 984, our Paris correspondent called attention to the fact that M. Chaleix-Vive has carried out a further series of observations upon the value of the administration of placental tissue to nursing mothers for the purpose of increasing the supply of milk. In the year 1898 M. Iscovesco published some experiments tending to show that placental tissue produces such an effect when given in small doses, whilst a very interesting paper upon the whole subject appeared last year in the March number of *L'Obstétrique* from the pen of M. Bouchacourt. In these days of organotherapy it is interesting to note that placental tissue or placental juice played an important part in the pharmacopœias of 100 years ago. Indeed, much earlier than this these substances were held in great esteem by many primitive people for the treatment of the most varied disorders. As might be expected the placenta was considered of especial value as an aphrodisiac and in the treatment of sterility in the female, whilst it was a common remedy in cases of epilepsy, apoplexy, and infantile colic. In the last disease the cord was also employed and a piece of it powdered was either given internally or placed as a poultice on the child's abdomen. No doubt on homeopathic principles a piece of placenta was often administered to the mother to prevent the retention of the after-birth or membranes after delivery, and amongst the Chinese it played an important part in the treatment of chlorosis. In this connexion it is interesting to recall the investigations of Stieda who has attempted to show that severe chlorosis is associated with imperfect development of the genital organs and breasts. Amongst the natives of the Philippine Islands it is still the custom for the mother after her delivery to burn the placenta, to collect the ashes, and to swallow them with a little water so as to insure the health of her child. The custom almost universal amongst the lower animals of eating the secundines is well known and the observation of the fact that it is followed by no ill results may well have led the primitive savage to employ the after-birth both as a food and a medicine. Various attempts have been made to explain this curious custom. It has been attributed to the promptings of hunger, to the desire on the part of the animal to hide all traces of its recent confinement so as to protect its newly born young from their enemies, or to the natural instinct that leads the mother to remove all traces of blood and dirt from her young and from her lair or nest. In administering the placental tissue as a galactagogue M. Bouchacourt used a preparation which he called "chorionine. This is obtained by washing the minced placenta of the sheep in running water and then submitting it to pressure. M. Chaleix-Vive has employed a glycerine extract of fresh sheep's placenta and reports that he has obtained very good results by its use. In endeavouring to estimate the value of this latest development of organotherapy the chemical composition of the placenta is a point of much interest. The recent researches of Sfameni and others have largely increased our knowledge upon this subject. He has shown that freed as far as possible from blood the human placenta contains a considerable quantity of phosphorus, phospho-carnic acid, various soluble albuminous bodies in small quantities, and salts of potassium and sodium, the latter in excess. In order to come to any real conclusion as to the therapeutic value of this tissue analyses of both the dried extract and of the glycerine extract should be carried out. No doubt such analyses would show that they contained most of the above substances. If this were so then it would be difficult to escape the belief that equally good results could be obtained by the administration of extracts of approximately the same chemical composition obtained from any other tissue of the body. A good deal of further evidence will be required before we can accept the statement that placental tissue has any definite specific action as a galactagogue. If the conjecture, however, for at the present time it can hardly be called more than a conjecture, that the placenta has an internal secretion should turn out to be a true one then it may well be that placental tissue will play an important part in the future treatment both of maternal and of fœtal diseases.

PUBLIC HEALTH IN NATAL.

NATAL became a British colony in 1856 and in 1893 it was provided with a new constitution, a governor, a ministry, and a legislative assembly. It was, however, only in 1901 that the first Public Health Act of Natal was passed. The Act became law in September of that year and one of its results is the publication of the first annual report of the department of public health, dealing with the events of the year 1902. In this report Mr. Ernest Hill, the health officer of the colony, candidly acknowledges that the numerical returns which form the basis of his statistics "are deficient in many respects because of the different systems of registration or the absence of any." Under the new Act births and deaths among natives are registered, but for statistical purposes the returns are of no value because the number of the population is not exactly known and the cause of death is assigned according to the statement of natives only. Even in registering the deaths of Europeans there is much laxity because no medical certificate is required, and the report states that in some parts of the colony it is not unusual for a medical practitioner to give a certificate as to the cause of death of a person whom he had not seen during life. Subject to these reservations Mr. Hill has compiled several tables and charts showing rates of mortality from various causes. The total "European" population of the colony has been taken as 74,600 persons, of whom 51,420 were in the towns and 23,180 were in the country. Among the total "European" population there were 1078 deaths—i.e., 14·4 per 1000—and 3086 births—i.e., 41·3 per 1000. For the town populations the death-rate was 16·1 per 1000 and the birth-rate was 33·1 per 1000; for the country population the death-rate was 10·7 per 1000 and the birth-rate was 59·5 per 1000. Among the "European" population the death-rates per 1000 from tuberculosis and cancer were 1·4 and 0·53 respectively. The local authorities show a conspicuous disregard of such questions as the removal and proper disposal of night soil and rubbish, the abatement of offensive and dangerous nuisances, and the supervision of slaughter-houses, cowsheds, and dairies. Enteric fever has since the war assumed a considerable degree of importance in places where it was previously almost unknown. Plague appeared in Durban at the beginning of December and 15 cases occurred during that month. Tuberculosis and syphilis are said to be increasing among the natives and a beverage called "tshimeyana," the nature of which is not described, is said to be producing serious effects among them.

THE CASE OF DR. LACHLAN GRANT.

THE latest development in the matter of the Ballachulish quarries dispute is that the quarrymen held a meeting on Oct. 5th at which certain proposals submitted to the directors of the company were read. Of those which particularly interest us from a medical point of view were (1) that the interdict against Dr. Lachlan Grant should be withdrawn; (2) that the medical appointment should be in the men's hands; and (3) that no deductions were to be made for medical attendance without the men's express consent. Among other proposals an increase in wages was asked for—viz., that labourers' wages should be increased in winter to 20*s.* and in summer to 22*s.* per week, while quarrymen should be paid as in other slate quarries—viz., "30*s.* per week in failure of contract." The above proposals were considered by the meeting and were carried with applause. On Oct. 8th the manager posted up a notice at the quarries informing the men that he had succeeded in arranging various terms with the proprietors of the quarries among which were the following. That the men should resume work on Oct. 12th under the same rules and conditions as existed in the works on resumption of work in January, 1902, "excepting that no doctor's fees will be collected unless it is otherwise arranged between the men and the manager." Wages were to be 28*s.* per week for quarrymen, with powder allowed, and 20*s.* a week for labourers all the year round. These proposals were considered by the quarrymen on the evening of Oct. 8th and the meeting unanimously refused to accept the terms offered. The men urged that only one point was touched upon in the company's notice—viz., the wages question—and the question of the medical man was left unsettled. The men are still standing firmly by Dr. Grant, as they have been doing for the last 15 months, and for nearly ten months they have been locked out, but up to now practically all of them have obtained work somewhere else so that no great loss has been incurred by them. The company has conceded one point in proposing that the men should be allowed to start work without insisting on deductions for medical attendance and medicine. We may therefore hope that if the men find themselves able to continue their loyal attitude towards Dr. Grant the company will eventually concede the demands of the men on this point also.

CLEANSING OF THE PERITONEUM.

IN the Mirror of Hospital Practice in this issue of THE LANCET is the report of a case of removal of an ectopic gestation by Dr. D. Lloyd Roberts. In his remarks on the case Dr. Lloyd Roberts expresses a preference for irrigation in cleansing the peritoneum when many small clots and much fluid are present. For many years the relative values of sponging and irrigating for the purpose of cleansing the peritoneum have been discussed and even now no unanimous decision has been reached. Irrigation at first sight appears to be the more likely to prove useful for it would seem that it would not be difficult to wash out the whole peritoneal cavity, but experience shows that it is practically impossible in most cases to cleanse the peritoneum by this method; this is very obvious when at a necropsy an attempt is made to wash out the peritoneal cavity. The innumerable pouches shelter much of the material which it is desired to wash away, in spite of very thorough irrigation. Exceptionally, however, there occur cases in which irrigation is capable of efficiently cleansing the cavity. These are instances where much fluid is present and very little adherent exudation, as in the case to which we have referred above. Especially is this so if the fluid is not primarily septic, as in cases of ectopic gestation, for then it matters comparatively little that some of the fluid should be left behind in the peritoneal cavity. In cases, however, where there is much adherent exudation on the surface of the bowel irrigation is of very little value, for it fails utterly to displace the adherent flakes. In these cases swabbing must be employed but the area of peritoneum is so large that to cleanse thoroughly the whole surface is a very tedious task. Fortunately the peritoneum possesses the power of dealing with a certain amount of microbic infection and no surgeon will maintain that by any method that we possess is it possible to render aseptic the peritoneum when its whole surface has become infected.

THE UNCONTROLLED USE OF PRESERVATIVES IN FOOD.

IT is a very regrettable fact that this country is still without any legislative control over the use of antiseptics for the preservation of food and the practice goes on to all intents and purposes unchecked without any regard to the mischief that may be done to the infant, to the invalid, or indeed to the healthy. It is now very nearly seven years since THE LANCET in the report of its Special Sanitary Commission on the Use of Antiseptics in Food drew attention to the necessity of placing some restriction on the kind and amount of chemical agents used very widely for the purpose of preserving food. It is just over four years ago—that is, in July, 1899—that a departmental committee was appointed to inquire into the subject. This committee occupied a considerable amount of time and it must be admitted that the members had a very big task before them. Finally, in November, 1901, very nearly two years ago, the conclusions and recommendations of this committee were made public by the usual channel of a blue-book. Since then absolutely nothing has been done to embody these recommendations, good and reasonable as they are, in the form of a statute and the art of preserving foods still goes on without let or hindrance. It is true that prosecutions have been undertaken but their success has depended upon individual opinions which in many cases have failed to convince the magistrates. The subject ought long ago, as we have urged again and again, to have become part and parcel of the provisions of an Act. We repeat that it is disgraceful that in spite of the careful consideration which, during two years, was given to the question by a committee of experts and of the fact also that its conclusions were made known nearly two years ago, we are still without the necessary statutory powers to control the practice of preserving foods. The delay is unjustifiable and perilous to the health of the community and we fail to see the reason for it.

THE SENSIBILITY OF THE VISCERA.

SOME interesting observations on the sensibility of the viscera have been made by Dr. K. G. Lennander and are recorded in the *Mittheilungen aus dem Grenzgebieten der Medicin und Chirurgie*, Band x., 1902, Hefte 1 und 2. As a result of an investigation of various viscera during the course of cases of operation he states that the parietal peritoneum is very sensitive to all operative measures but that the intestinal canal, the mesentery, the stomach, the anterior margin of the liver, the gall-bladder, the urinary bladder, and the parenchyma of the kidney are completely insensitive to all manipulative procedures and even to the thermo-cautery. The parietal peritoneum itself appears to be sensitive only to painful and not to tactile or thermal stimuli; this sensibility to pain Dr. Lennander attributes to twigs of the intercostal nerves in the subserous areolar tissue. The lungs and the anterior wall of the trachea are also insensitive. The mucous membrane of the rectum is likewise insensitive to all ordinary stimuli but if its lumen be distended to a diameter of three and a half to four centimetres a desire to defecate is produced. Again, the testes and epididymis are insensitive while their coverings are sensitive. Dr. Lennander infers that organs which are innervated from visceral nerves alone are insensitive, while those having branches supplied to them from somatic nerves are sensitive. There is perhaps little that is new in these observations of Dr. Lennander or in his interpretation of them but they lend strong support to the view that at any rate some sensations of pain depend upon nerve fibres anatomically distinct from those subserving tactile and other cutaneous sensations, since the parietal peritoneum is apparently sensitive to painful stimuli only. At the same time that diseased or injured viscera may give rise to painful sensations interpreted locally—that is to say, apart from, or in addition to, referred pain and tenderness—is a matter of daily observation and this variety of pain is usually regarded as due to an exaggeration or augmentation of the common sensibility of the part, of which in health there is no conscious appreciation.

DETERMINATION OF FAT AND TOTAL SOLIDS IN MILK.

IN the August number of the *Archives of Pædiatrics* Dr. Henry L. K. Shaw of Albany, New York, gives details and results of a number of comparative experiments made with different processes for the determination of the fat and the total solids in milk. He first describes the Babcock method of determining fat, a method which, he says, is distinctively American and is widely employed by American dairymen. It requires a centrifuge and at his suggestion a small one has been manufactured for the use of medical men. The process is as follows: 17·5 cubic centimetres of milk are first measured into the test bottle and 17·5 cubic centimetres of sulphuric acid of specific gravity 1·082 are then slowly added. The milk and acid are thoroughly mixed by a rotary motion, placed in the centrifuge, and whirled for four minutes. Boiling water is then added by means of a pipette until the lower part of the column of fat comes within the graduated scale on the neck of the bottle. A second whirling for one minute completes the separation of the fat. The fat thus obtained should form a clear yellowish liquid quite distinct from the acid solution and the height of the column is then read off. The Marchand lactobutyrometer, he says, is better known abroad than in America. It consists of a glass tube closed at one end, with a narrowed segment near the open end. The narrow portion is graduated into 30 divisions. The tube is marked so that the lower portion shall contain five cubic centimetres of milk, the middle portion five cubic centimetres of ether, and the upper portion five cubic centimetres of alcohol. The milk is first introduced up to the point indicated in the tube and a few drops of a 10 per cent. solution of sodium hydrate are added, after which the ether is added and mixed, and the alcohol is then added and mixed. The tube is now immersed in a water-bath at 100° F. for 15 or 20 minutes and the amount of fat is read off from the scale. The other methods or tests made use of were the Gerber method, the Lefferman-Beam (? Leffmann-Beam) test, and the Holt cream gauge. The control estimations of fat, to be taken as the standard, were made in the laboratory of the New York State Department of Agriculture by the Adams extraction method. This consists in spreading the milk over absorbent paper, drying and extracting the fat with ether in a Soxhlet apparatus. The ether is removed by distillation and the fat in the flask is weighed. The process is a good one but is too tedious and complicated for medical use. A comparison of the results of the experiments, 30 in number, showed that the Babcock test could be relied on for accuracy and was the most suitable of all for medical use. Dr. Shaw estimates the total solids from the specific gravity of the milk and the percentage of fat, using a special form of slide-rule for the performance of the necessary calculations.

MEDICAL CONGRESSES IN ITALY.

THE Thirteenth Annual Congress of Internal Medicine will take place this year at Padua from Oct. 29th to Nov. 1st under the presidency of Professor Guido Baccelli. In addition to other subjects which may be brought forward by any of the members of the Congress three selected themes have been put down for discussion—namely (1) the Influence of Individuality in the Pathogenesis and the Ætiology of Disease, to be opened by Professor A. de Giovanni and Professor L. Giuffrè; (2) Immunity in Acute Infective Diseases, to be opened by Professor Lucatello and Professor N. Pane; and (3) the Medical Indications for the Interruption of Pregnancy, to be opened by Professor Zaggri and Professor V. Ascoli. The Congress of the Italian Pathological Society was held in Florence from Oct. 5th to 7th under the presidency of Professor Pestalozza. An important paper was read by Professor Foà upon Cytotoxic Serums. Various papers were contributed by the Roman school; amongst others one upon Sclerosis of the Coronary Arteries by Professor Marchiafava, another on the Alterations of the Nerve Centres consecutive to Infantile Cerebral Lesions by Professor Bignami, and another on the Acute Ascending Paralysis of Landry by Dr. Nazari. Before closing it was decided to hold the next Congress in Milan in the spring of 1905 and to endeavour to transform the society from a national into an international one, Professor Foà and Professor Golgi being appointed to approach the Pathological Association of Germany with the object of bringing this about. At Messina there will be held in the first half of November the National Congress for the Hygiene of the Alimentation and Care of Early Childhood.

REPORT OF THE MINER'S PHTHISIS COMMISSION IN SOUTH AFRICA.

THE report of the commission which was appointed in 1902 to inquire into, and to report on, the disease commonly known as "miner's phthisis" has now been issued together with the minutes of the proceedings and the minutes of evidence. The terms of reference were as follows: (1) to inquire into the extent to which miner's phthisis prevails; (2) to ascertain the cause of the disease; and (3) to make recommendations as to the preventive and curative measures which should be adopted either by legislation or otherwise. The evidence adduced and the deductions therefrom form interesting reading. It appears that the disease is largely confined to miners who have worked for some time in metalliferous mines and is chiefly noticeable among the rock drill miners of the Witwatersrand gold mines. It was further shown that the disease prevails to a very great extent and that a high mortality is due to it. The commissioners were fully convinced that the pathology of the condition is a silicosis produced by the inhalation of minute particles of inorganic matter with which the atmosphere of the mine is naturally charged. This conclusion was the only one to be expected and the chief interest in the report lies in the suggestions which are made for the protection of the workmen. Valuable investigations were made as to the composition and quantity of the air circulating throughout the working places in the mine and as to the composition of the gases given off during blasting operations in varying circumstances. It was also found that the sanitary state of the mines left much to be desired and that the conditions under which the miners lived were not satisfactory. Efficient "change houses" were not provided in many of the mines, so that the men could not obtain facilities for washing and for changing and drying their clothes The commissioners therefore are of opinion that it is urgently necessary to prevent as far as possible by means of sprays and jets the discharge of the minute angular particles of dust into the atmosphere of the mine; to supply the working places throughout the mines with air in sufficient quantities and in such a manner as to render harmless, and to sweep away, the vitiated atmosphere; to maintain underground workings in a clean condition and to institute for this purpose a suitable sanitary system; to provide "change houses" properly warmed and within reasonable distance of each shaft; and to avoid the use of low flash-point lubricants in the air cylinders of compressors. These are practical points the enforcement of which would go far to mitigate the danger to which the workmen are exposed. It is to be hoped that regulations formed with a view to carry out these suggestions will be formulated as speedily as possible.

THE INFLUENCE OF SEASON ON THE OCCURRENCE OF GLAUCOMA.

THE influence of temperature and of season on the supervention of attacks of acute glaucoma is the subject of a communication by Dr. Kurt Steindorff to the *Recueil d'Ophtalmologie* for September. This seems to be a point in the etiology of glaucoma to which but little attention has been directed. It is not mentioned in Norris and Oliver's "System of the Diseases of the Eye" under the article on glaucoma written by Mr. Priestley Smith. Fuchs, Panas, and Swanzy are silent upon the subject, yet, as Dr. Steindorff observes, Hippocrates long ago drew special attention to the influence of temperature and of season on the number of cases and the variety of affections of the eye, whilst support is given to his statements by recent bacteriological researches which show that certain ophthalmic affections are attributable to micro-organisms and that the conditions most favourable for the growth and development of these bodies are coincident with the outbreak of the several diseases which they are believed to occasion. Dr. Steindorff, working in Professor Hirschberg's clinic at Berlin, has had the opportunity of studying that distinguished ophthalmic surgeon's case-books and finds that between May 1st, 1885, and April 30th, 1902—that is, during 17 years—there have been under treatment 7101 patients amongst whom there were 83 patients with acute primary glaucoma, the number of eyes affected being 102. The disease occurred more frequently in women than in men, the proportion being 64 to 19, or 77·1 per cent. By far the most frequent age was the period between 50 and 70 years. Some, perhaps ten, of the 102 cases should properly be excluded because the attack was directly induced by the use of mydriatics in an eye already predisposed to the disease or resulted from operation on the opposite eye. Of the 92 remaining cases 68 were utilisable as showing the effects of meteorological influences, since they occurred in Berlin where the weather reports of the period were accessible. On examining the dates of the attacks of the entire number of 102 cases it was found that 65 cases occurred during the cold period of the year—that is, from October to March—whilst there were only 37 cases from April to September. Of the cases that presented themselves in summer the larger number occurred on the hottest days. Dr. Steindorff calls attention to the well-known influence of cold on blood pressure and therefore on the intra-ocular tension, an influence that is particularly well-marked in those suffering from the arteriosclerosis which is frequently associated with glaucoma. Very high temperatures, on the other hand, have a tendency to lower the force of the heart and to lead in this way to venous stasis. No relation was observed between the attacks of glaucoma and the humidity of the air, the force or direction of the wind, or to storms.

LEUCOCYTOSIS DURING DIGESTION.

IT has long been admitted that during the process of digestion an increase takes place in the number of leucocytes to be found in the blood, but the period of digestion when this increase occurs, the extent and duration of the increase, and the characters of the leucocytes, as well as their source or sources, have not been satisfactorily ascertained. Nor has the effect of the presence or absence of the spleen been determined. The inquiry is a difficult one but it has been attacked by three physiologists working in concert and the results of their experiments have been published in a recent number of the *Journal of Physiology* (vol. xxx., No. 1). The enumeration of the leucocytes was undertaken by Dr. Alexander Goodall, the differential counts were made by Dr. G. Lovell Gulland, whilst to Dr. D. Noel Paton was intrusted the operative part of the proceedings, as the withdrawal of the blood, the removal of the spleen, and the determination of the hæmoglobin. Eight experiments were made, seven being upon dogs and one upon a cat. In each case the animal was kept fasting for a day; a little blood was then withdrawn and the number of leucocytes in a definite quantity was determined by means of the Thoma-Zeiss leucocytometer, whilst simultaneously the amount of hæmoglobin was determined with Oliver's hæmoglobinometer in order that any error arising from differences in concentration of the blood might be excluded. The animal was then fed on as much minced beef and water as it would eat. The experiments showed that there was a tolerably regular rise in the total numbers of leucocytes in the circulation and that this increase reached its maximum about four hours after the ingestion of food. The increase is due partly to a lymphocytosis which is very constant as regards its incidence and degree and partly, in the greater number of cases, to a much more variable polymorphonuclear leucocytosis. Leucocytosis during digestion is not affected by removal of the spleen. The organs to which these experimenters attribute the increased numbers of the leucocytes during and after digestion will constitute the subject of another communication.

THE winter course of lectures and demonstrations in connexion with the Mount Vernon Hospital for Consumption and Diseases of the Chest was opened on Oct. 15th by Professor Thomas Oliver of Newcastle-on-Tyne with an address on Occupation as a Cause of Lung Disease. The lectures are free to qualified practitioners and students of medicine and are given in the lecture hall of the out-patient department at 7, Fitzroy-square, London, W., on Thursday afternoons at 5 o'clock. A full list of the forthcoming lectures will be found in our advertisement columns.

A SPECIAL meeting of the council of the Charity Organisation Society will be held on Monday, Oct. 26th, at 4 30 P.M., at the Royal United Service Institution, Whitehall, London, S.W., when Dr. Edmund Cautley will read a paper on Outpatient Departments and the Rearing of Children. Sir W. J. Sendall, G.C.M G., will take the chair. Communications should be addressed to the secretary of the society, 15, Buckingham-street, Strand, W.C.

ONLY 1 case of plague was discovered in the Cape Colony during the week ending Sept. 26th—namely, at Port

Elizabeth. Plague infected rats were found in the dock at East London. In the Mauritius for the week ending Oct. 15th there were 88 cases of plague and 54 deaths from the disease.

H.R.H. the Princess of Wales has graciously consented to become patron of the British Lying-in Hospital (founded in 1749), the oldest hospital of its kind in London.

WE regret to announce the death of Dr. James Robert Wallace, editor of the *Indian Medical Record*, which took place in India on Sept. 27th.

DINNER OF THE ROYAL ARMY MEDICAL CORPS.

SPEECH BY MR. BRODRICK.

Surgeon-General Sir William Taylor, K.C.B., Director-General of the Army Medical Department, presided at a dinner given on Oct. 21st at the Whitehall Rooms, Hôtel Métropole, London, by the Royal Army Medical Corps, the guests being the Right Hon. St. John Brodrick, the Secretary of State for India.

Sir WILLIAM TAYLOR, after proposing the usual loyal toasts, spoke to the toast of "The Guests." He said that Mr. Brodrick's Reorganisation Committee had introduced many improvements into the medical service of late Amongst these was the issue of a new Warrant and among the benefits resulting therefrom was increased pay, not only for those serving in the United Kingdom but also for those serving in India and the colonies. By the new Warrant charge pay was also given; that had been asked for times without number but had always been refused until insisted upon by Mr. Brodrick's committee There was, further, an increase under the new Warrant of examinations, and when he reminded them that passing these examinations brought with it increase of pay and accelerated promotion he thought no one would deny that that also was of benefit He drew attention particularly to the appointment of sanitary officers to insure healthy quarters and camps. Another result was the removal of the Royal Army Medical Corps school from Netley to London. They were indebted to Mr. Brodrick for the sum of £100,000 voted for the new building. A large increase had been made to the nursing establishment of the corps, resultin [illegible] idition of the wards and of [illegible]. One of the most useful c [illegible] was that on army organisation and he asked if it was not possible to make these lectures more widely useful and to devise some method of registration by which the services of civilian medical men trained for war could be secured.

Mr. BRODRICK, in replying, commented on the great reductions in the Army Medical Department which were carried out in 1886 and which they had ever since had good reason to regret This reduction occurred at a time when the civilian members of the profession were making rapid advances in scientific knowledge. He then proceeded to show its result by quoting the number of entrants for the examinations to the Royal Army Medical Corps and the number of vacancies for a few years back. In 1897 the candidates numbered 28 and the vacancies 35; in 1898 there were 21 candidates and 40 vacancies; in 1899 there were 25 candidates and 28 vacancies; and in 1900 there were 16 candidates and 50 vacancies In 1902, after the reorganisation of the Royal Army Medical Corps, there were 73 candidates for 30 vacancies; in February last there were 50 candidates for 30 vacancies and 78 candidates for 30 vacancies in July last. Mr. Brodrick said that it needed no word from him to point the moral conveyed by these figures. During the late war some people had been surprised that the Royal Army Medical Corps had not expanded to meet the great emergency of that time. But, he said, if on the occasion of the banquet at which they were present instead of inviting 100 guests they had only asked 30 and had called on the cook late in the afternoon to provide for 100 they would not have found fault with the cook but with the man who ordered the dinner if matters had not turned out satisfactorily. Until lately the Royal Army Medical Corps had not been able to keep pace with the advances in medicine because there were no examinations for special promotion and even high positions were filled by men who were chosen in order of seniority and without any selection for merit. There was no study leave granted for scientific research and owing to the shortage in officers the amount of foreign service was excessive Without the coöperation of the civilian heads of the profession and without the free acceptance by the Army Medical Department of the help offered to it the great development and changes in the Royal Army Medical Corps could not have taken place. He considered that the substructure on which any Minister would in future have to work if he wanted to make progress in army matters would be the hearty coöperation of those who had given the orders with those who had to carry them out. Mr. Brodrick then described the friction that he found at the War Office 17 years ago between the civilians and the military men and contrasted that condition of things with those prevailing at the present time when the greatest cordiality prevailed. He failed to find on looking through the pages of the report of the Royal Commission any complaint that the civilian element had broken down. He particularly emphasised the point that the Royal Army Medical Corps had been brought into close touch with the outside world of science and he hoped that the new college of the corps would be rising from the ground within a few months. The money had been voted and the necessary plans had been prepared.

Sir WILLIAM S CHURCH, Bart., K C.B, who also replied to the toast, said that the Royal Army Medical Corps had been enabled to meet the unprecedented demands made on it in the late war in a way that surprised him and his brother commissioners because it had a vast amount of trained material on which to draw, though there was a lack of knowledge of military organisation

Sir LAMBERT H. ORMSBY, President of the Royal College of Surgeons in Ireland, and Sir WILLIAM TURNER, K.C.B., President of the General Medical Council, having also responded, Sir FREDERICK TREVES, Bart, K.C.V.O., proposed the toast of "The Royal Army Medical Corps," which was acknowledged by Sir WILLIAM TAYLOR, and this concluded the evening's proceedings.

THE ROYAL COLLEGE OF SURGEONS OF ENGLAND.

A QUARTERLY meeting of the Council was held on Oct. 15th, Mr. JOHN TWEEDY, the President, being in the chair.

The Secretary reported the death on Sept. 6th, at the age of 66 years, of Mr. Thomas Richard Jessop, member of the Council, and he stated that the President had attended the funeral at Leeds as the representative of the College.

The following motion was passed :—

[illegible]

The Secretary also reported the death on Oct. 12th of Mr. George Lawson, past member of the Council, and a vote of condolence was passed.

A letter was read from Mr. T. Pickering Pick resigning his seat on the Council. The Council accepted the resignation with regret and expressed its feeling of appreciation of the many services rendered to the College by Mr. Pick during his tenure of office as member of Council and of the Court of Examiners.

The PRESIDENT stated that the vacancies on the Council so occasioned would be filled up at the July meeting of the Fellows

A report was read from the Museum Committee reporting the completion of the redecoration of rooms 2 and 3 of the museum.

Mr J. Langton was re-elected a member of the Committee of Management.

Mr. Rickman J. Godlee was elected a member of the Laboratories Committee in the vacancy occasioned by the retirement in rotation of Mr. Henry Morris.

The draft copy of the annual report of the Council was approved.

The following motion was adopted :—

The attention of the Council having been called to the fact that medical certificates are not infrequently made use of by soldiers to assist them in deserting and otherwise evading military discipline the Council desire to call the attention of Fellows and Members to the abuse to which such certificates may be put and to the responsibility which is attached to their issue.

This motion was adopted by the Council in consequence of the following report received from the Discipline Committee, viz. :—

The committee desire to report to the Council that they have had under consideration a communication from an officer in command of a battery of Royal Field Artillery at Aldershot stating that "it is a notorious fact amongst soldiers that a certain class of practitioner will grant a medical certificate to enable a soldier to remain absent on insufficient grounds," that several instances have recently come under his notice, and that in two cases the certificate has assisted the soldier to desert and to conceal his desertion for several days. The officer in question also submits full particulars of one case, from which it would appear that a driver in his battery obtained a certificate of this nature upon insufficient grounds. Without questioning the *bona fides* of the practitioner who granted the certificate in the particular instance to which their attention has been called, the committee, in view of the alleged frequency of such cases, would suggest to the Council the desirability of calling attention to the abuses to which medical certificates may be put.

A letter was read from the President of the General Medical Council stating that he had been authorised to appoint a committee of members of the General Medical Council to confer with representatives of the Royal College of Physicians of London and the Royal College of Surgeons of England in regard to the questions which have been raised respecting the regulations for the first year of study and the first examination of the Conjoint Examining Board and asking to be informed if the College desires such a conference and will appoint representatives.

It was resolved to inform the President of the General Medical Council that his letter had been under prolonged discussion and that a committee had been appointed to confer with representatives of the Royal College of Physicians of London on the subject of the proposed conference.

A letter was read from Mr. Reginald Harrison offering to present to the Council a collection of photographs of the Honorary Fellows of the College. The offer was accepted and the best thanks of the Council were voted to Mr. Harrison for his interesting gift.

Mr. Dent was appointed a member of the Finance Committee and Mr. A. W. Mayo Robson was appointed a member of the Discipline Committee in the vacancies occasioned by the death of Mr. Jessop.

The Council passed the following motion as a reply to a request from the solicitors of the Worshipful Company of Spectacle Makers for the views of the Council on a proposed inclusion of sight-testing in the examination for the diploma of the company :—

The Council of the Royal College of Surgeons have carefully considered the matters upon which they have been invited by the Worshipful Company of Spectacle Makers to express their opinion and desire to submit the following statement of their views for the information of the committee appointed to consider the proposed alteration in the character of the company's diploma :—

Considering the hidden danger and the untoward possibilities that may attend almost any morbid state of the body it is against public safety and welfare that anyone should be deemed competent to order or prescribe any medical or surgical remedy or appliance who has not had an efficient medical and surgical training. More particularly with respect to the petition of working opticians that they should be certified, after due examination, to be qualified to test the sight and prescribe spectacles to correct the various errors of refraction, it is to be observed that, while optical defects often occur in eyes which are otherwise healthy, they are not infrequently associated with diseased conditions which are difficult to detect and whose nature and significance can only be appreciated by persons who have studied diseases of the eye not merely as local affections but in their relation to general disease. Moreover, in many grave affections of the eyes, whether of a local or of a constitutional character, such as inflammation or atrophy of the optic nerves, inflammation or degeneration of the retina or choroid, chronic glaucoma and many other diseases, the earliest and most obtrusive symptom is often impairment of sight, which patients themselves are too prone to ascribe to presbyopia or other optical defects remediable by spectacles. This opinion, the optician, by virtue of his calling, is naturally predisposed to adopt and enforce. In the ultimate interest of the public no countenance should be given to any proposal which is likely to foster the belief that tradesmen, whatever be their technical skill, and whether opticians or orthopædic or other surgical instrument makers, are safe and sufficient guides in the management and treatment of deformities or other diseased conditions.

Obituary.

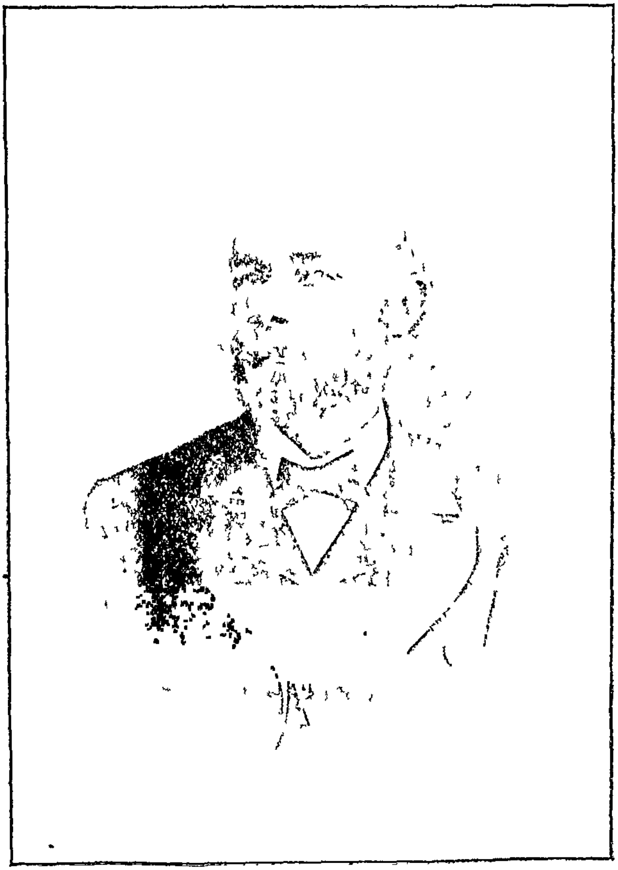
GEORGE LAWSON, F.R.C.S. ENG.,

CONSULTING SURGEON, ROYAL LONDON OPHTHALMIC HOSPITAL, MOORFIELDS, AND THE MIDDLESEX HOSPITAL; AND SURGEON OCULIST TO HER LATE MAJESTY QUEEN VICTORIA.

Mr. George Lawson, whose death on Oct. 12th in his seventy-third year we recorded in our last issue, was a man who endeared himself to all who knew him—to his patients, to his colleagues, to his pupils, to his nurses, and also to the porters and the servants of the institutions with which he was connected. His peculiar freshness and charm of manner, his evident sincerity, and complete unselfishness impressed themselves on all who came in contact with him. He was born on August 23rd, 1831, being the second son of William Lawson of the firm of Trower, Trower, and Lawson of the City of London. He received his general education at Blackheath and King's College and his professional training at King's College Hospital. He there came under the influence of Sir William Fergusson who was at that time attracting so much attention by his brilliant operative dexterity. Mr. Lawson became his house surgeon and in a surgical sense may be considered as one of his descendants, whilst in ophthalmology he followed in the footsteps of Sir William Bowman who during Lawson's student career was an assistant surgeon at King's College Hospital.

Mr. Lawson qualified as a Member of the Royal College of Surgeons of England when 21 years of age and the following year obtained the diplomas of Licentiate of Midwifery and Licentiate of the Society of Apothecaries. Early in 1854, war threatening to break out between England and Russia, Mr. Lawson, full of surgical ardour, entered the army as an assistant surgeon and was gazetted on the army medical staff. In March of that year he left England with the first batch of troops for Malta and was there when war was declared. He then accompanied the troops to Gallipoli and afterwards to Varna where he was attached to the third division under General Sir Richard England to attend the staff and those connected with them. From Varna he went to the Crimea and landed with the troops at Old Fort, being exposed to the drenching rain which rendered famous the first night of the Crimean campaign. He marched with the army and saw the first shot fired at the Bulganak. He was at the battle of the Alma, in the flank march which followed some days afterwards, and with the rearguard at Mackenzie's farm. He was also with the third division in front of Sebastopol and on Nov. 5th at the battle of Inkerman was detached to do duty with the fourth (Sir George Cathcart's) division. About the middle of January, 1855, Mr. Lawson was sent to Balaclava as assistant to Dr. Arthur Anderson to attend to the sick officers on board ship and the sick of the staff and commissariat. Towards the end of May, 1855, he caught typhus fever from some mule drivers whom he was attending; in July he was invalided to England and sent home in charge of one of Miss Nightingale's nurses. During 1855 he had been gazetted assistant surgeon to the 3rd Battalion Rifle Brigade. After an illness of five months, the Crimean war having ended, he retired from the army. Throughout the rest of his life he always took the greatest interest in the service and kept a warm place in his heart for any soldier who came under his care He would often take great trouble in helping those who were injured or disabled to acquire an adequate pension or compensation. Mr. Lawson never completely recovered from the effects of the fever—his circulation remained permanently impaired. His pulse-rate was always remarkably slow and his hands were cold and livid. Those who have followed him round the hospital will recall the frequent pauses that he made in ascending any stairs, pauses always enlivened by charming conversation on the wide and diverse subjects in which he was interested.

On giving up the army Mr. Lawson decided to practise in London; he passed his examination for the Fellowship of the Royal College of Surgeons of England in 1857, settled at first at 63, Park-street, Grosvenor-square, and as the outcome of his experience at the Crimea wrote a pamphlet "On Gunshot Wounds of the Thorax" which appeared in 1858 From about this time he began to turn his attention specially to ophthalmic medicine and surgery, influenced probably by Bowman whose clinical assistant he became at the Royal



GEORGE LAWSON, F R.C S

London Ophthalmic Hospital, Moorfields. In 1861 appeared the first of a long series of communications which he contributed to that hospital's Reports; it was the description of a case of congenital absence of the iris. For a short time he held the post of surgeon to the Great Northern Central Hospital. In 1862, on the retirement of Mr. Poland, he was appointed assistant surgeon to Moorfields Hospital and the following year assistant surgeon to the Middlesex Hospital. At each of these two latter institutions he continued to work until he became the senior surgeon and reached the retiring age.

During the first years of his connexion with Moorfields Hospital he devoted particular attention to injuries of the eye and sympathetic ophthalmitis. Several papers were written by him on these subjects in the Ophthalmic Hospital Reports and a pamphlet on the latter was published in 1865. The importance of removing injured eyes or atrophied blind eyes, which were at all likely to endanger the safety of the other eye, was a topic upon which Mr. Lawson was particularly fond of dilating. In 1867 he published his collected experiences on these matters in a book entitled "Injuries of the Eye Orbit, and Eyelids." Two years later appeared the first edition of his "Manual on Diseases and Injuries of the Eye," by which he became widely known outside his own school. It was a book which certainly "hit the moment" and ran rapidly through several editions. It supplied in a most readable form a thoroughly practical work on a special subject suitable for a student. Up to that time no work covering quite this ground had appeared in English, though several books on similar lines have since been written. This year a sixth edition of this work, edited, enlarged, and largely rewritten by Mr. Arnold Lawson, has been brought out. We know that the production of it by his son afforded Mr. George Lawson much zest and interest during his declining years. We are glad to see that in it has been retained much of the practical shrewd common sense which rendered Mr. George Lawson's treatment of patients so eminently successful. He did not stop in his treatment at simply prescribing drugs or lotions. He would instruct a mother how to feed, to clothe, and to train her child, often entering into much detail as to the preparation of the food. He would tell a patient in whom nothing could be done to restore sight what he could still do and how o get to work to earn a livelihood. Many of those who see ut-patients have doubtless wished that they could prescribe or some of them food instead of medicine. Mr. Lawson ctually did this, having an arrangement with a neighbourng butcher by which he could order patients so many pounds f meat. Nor did Mr. Lawson's generosity to out-patients nd with supplying sound advice and meat; many a patient o whom some more than usually disastrous circumstance had occurred would be led quietly aside and return with a miling face and a closed palm.

In his after-treatment of operation cases Mr. Lawson was ull of little devices calculated to further the convenience or welfare of his patients. The twisted wire sides for spectacles, which add so much to the comfort of those who have to wear hem constantly, were originally suggested by him. He had rapid and almost intuitive way of arriving at a diagnosis which was somewhat startling to those who failed to ppreciate the large amount of experience of which it was he outcome. As a general surgeon Mr. Lawson was a udicious, bold, and cool operator, ever ready to meet any mergency that might arise. He reached his zenith before he recent advances in abdominal operations had been ffected and during the latter part of his career he preferred o transfer cases requiring such treatment to younger hands. An operation at which he was particularly successful and dexterous was the removal of the upper jaw and as became a pupil of Fergusson he was a skilful lithotomist He had an exceedingly steady hand which was of special service to him in the delicate operations on the eye. He was an ardent advocate for the use of a Graefe's knife instead of a keratome in cases of glaucoma and preferred curette evacuation to suction for the removal of soft cataracts. It may be noted that Mr. Lawson was in the habit of saying that cataract operations caused him infinitely more anxiety than any general operative procedure. In diseases of the orbit he took a keen interest and his last contribution to ophthalmic literature was a paper on plastic cellulitis affecting that cavity, which he read at the Ophthalmological Society in December, 1894. He was a lecturer on surgery at the Middlesex Hospital. His teaching may be described as more picturesque than systematic. About matters which he felt strongly he was most emphatic and would illustrate them with a wealth of practical observations which could not fail to interest and to instruct.

Mr. Lawson was a difficult man to get the better of in an argument; when you thought you had got him completely in a corner he would in a most innocent manner by some happily expressed phrase or anecdote turn the conversation into an entirely fresh channel. For a time he was an examiner in surgery for the Royal College of Physicians of London but it was a form of employment in which he took but little delight. He was elected a member of the council of the Royal College of Surgeons of England in 1884 and in 1886, at the suggestion of Sir William Jenner, was appointed surgeon oculist to Her late Majesty Queen Victoria, which appointment he held until her death. Mr. Lawson took considerable interest in the improvement of his wards at the Middlesex Hospital and through the generosity of private friends and old patients he was enabled to effect many alterations in their furniture and structural arrangements which proved so advantageous that they were subsequently adopted throughout the hospital. During the later years of his connexion with the Middlesex Hospital he was largely instrumental in the establishment of the chapel. Always a strong Churchman, the superintendence of its erection and beautification afforded him the [illegible] ore fitting place than this chapel [illegible] memorial service at which his [illegible] assembled to take part on Oct. 16th.

Mr. Lawson was a man of very simple tastes, the state of his health incapacitating him from taking any active exercise. He was a great reader and exceedingly fond of animals. He would never allow [illegible] as a constant compani [illegible] and in the summer, h [illegible] large family of boys, [illegible] "The Hut" at the h [illegible] to recuperate from the fatigues of his very extensive private practice and hospital work. On his retirement from the Middlesex Hospital his old assistants and pupils, to whom he was always a staunch friend, wished to honour him by entertain [illegible] man and [illegible] nitely de [illegible] by the death of two of his sons, both of whom had passed through most distinguished careers at the Middlesex Hospital. He saw patients up to within 18 months of his death which occurred at his residence, 12, Harley street, Cavendish-square, on the afternoon of Monday, Oct. 12th, after a long illness.

His wife and five sons survive him; of these latter two are in the medical profession: one, Mr. Arnold Lawson, like his father, is practising as an ophthalmic surgeon and the other is a captain in the Royal Army Medical Corps. By the death of Mr. George Lawson the profession not only loses a most distinguished surgeon but a most generous large-hearted man who was the true type of a Christian gentleman. The funeral took place at Hildenborough on Oct. 16th.

DEATHS OF EMINENT FOREIGN MEDICAL MEN.—The deaths of the following eminent foreign medical men are announced:—Dr. Ernst Pflüger, professor of ophthalmology in the University of Berne. He was a pupil of Donders in Utrecht and of von Arlt in Vienna.—Dr. Domenico Tibone who has been for 38 years professor of midwifery and gynæcology in the University of Turin.—Dr. Ricardo Secondi, professor of ophthalmology in the medical school of Genoa.—Dr. Tschaussow, professor of anatomy in the University of Warsaw, at the age of 54 years.

MEDICINE AND THE LAW.

A Case of Selfish Recklessness.

ON Oct. 15th at the South-Western police-court a working-man in the service of the Battersea borough council was summoned for exposing himself while suffering from small-pox. He had been to a public-house and to the home of a friend while well aware of the fact that it was wrong for him to do so, for he had actually written at that time to someone saying that he was expecting to be removed to an isolation hospital. He was fined 40*s.* and costs, in addition to which he had been deprived of his wages by his employers during his illness in consequence of his conduct. It was stated on behalf of the Battersea borough council that men employed by the council and suspected of sickening with small-pox were, as a rule, treated by its medical staff and isolated without undergoing any loss of pay, so that there was no excuse for the defendant's recklessness.

A Question of Liability.

The Lord Mayor, sitting at the Mansion House, was informed recently of an objection raised by the City board of guardians to defray the cost of treatment in its infirmary of persons arrested on the Tower Bridge. The man in whose case the matter was mentioned had tried to commit suicide from the bridge and was rightly arrested by the City police in whose jurisdiction it is. The bridge, moreover, was erected by the corporation. It is, however, apparently contended by the clerk to the City guardians that for administrative purposes the Tower Bridge is in Whitechapel and that the person in question should have been handed over to the care of the Whitechapel guardians. The Lord Mayor seems to have felt no doubt that this contention was wrong but the question was not before him for decision. It was not suggested that the man, who was ill and in a very weak state, had in any way suffered from the difficulty which had arisen and the point will no doubt be finally settled before another similar case arises.

Horses and the Sausage Trade.

A man was awarded a month's imprisonment recently at the Thames police-court who was found leading a lame and diseased horse to Barking, presumably with a view to shipment to the continent. The magistrate, in sentencing him for the cruelty inflicted upon the animal, spoke of the trade for the benefit of which the poor brute was to be exported as the "organised sausage trade." The evidence of a veterinary surgeon was to the effect that the horse was so diseased that its flesh must be totally unfit for human consumption. Our foreign neighbours are not to be congratulated upon the articles of food manufactured from such animals, a proportion of which are, no doubt, imported to England.

THE PREVENTION OF CONSUMPTION AND OTHER FORMS OF TUBERCULOSIS.

NATIONAL ASSOCIATION FOR THE PREVENTION OF CONSUMPTION.

A MEETING of the council of this association was held at 13, Hanover-square, W., on Oct. 12th, Sir WILLIAM H. BROADBENT being in the chair. It was resolved that a committee to make arrangements for the forthcoming congress in Paris in 1904 should be appointed on which all the members of the council and a number of other gentlemen would be asked to serve. A letter from the Incorporated Society of Medical Officers of Health was read, also a memorial to the Principal Secretary of State for the Home Department with reference to the proposed standards of ventilation contained in the first departmental report on the ventilation of factories and workshops presented to both Houses of Parliament in 1902. The memorial expressed the hope that in the interests of public health a standard of ventilation for factories and workshops would be prescribed under Section 7 of the Factory and Workshop Act, 1901, which should not be lower than that now in force in humidified factories—viz., nine volumes of carbonic acid in 10,000 of air, or, preferably, five volumes of carbonic acid in excess of that found in the outside air at one and the same time. Further, that the standard adopted would not be lowered for gas- or oil-lighted factories and workshops in the way suggested in the first recommendation of the committee, such a lowering being entirely unnecessary in view of the fact that efficient means were at present known by which the products of combustion from gas or oil could be easily and readily removed by ventilating outlet tubes placed over gas-jets or oil-burners and communicating directly with the outside air. Indeed, the legislation of a standard as low as that suggested—viz., 20 volumes of carbonic acid in 10,000 of air in gas- or oil-lighted factories or workshops—would practically render all attempts at securing efficient ventilation nugatory. The council entirely endorsed this memorial and as it already has approached the Home Secretary on the subject it expressed its willingness to co-operate further with the Incorporated Society of Medical Officers of Health in any way that might be thought practicable. The council resolved, in view of the by-law against spitting recently passed by the London County Council, to take further steps to induce the railway companies to prohibit spitting in their carriages and about their premises.

Looking Back.

FROM

THE LANCET, *SATURDAY*, OCT. 22, 1825.

LECTURES

ON THE THEORY AND PRACTICE OF PHYSIC,

BY DR. CLUTTERBUCK.

Theatre, General Dispensary, Aldersgate-street.

LECTURE I.[1]

CHEMISTRY will make a part of this Course, (the materia medica,) because it is chiefly of importance in its relation to pharmacy. Chemistry, notwithstanding the vast advances it has made of late years, and the important applications that have been made of it in other arts, has still but a remote relation to medical science. It is of no service to us in regard to physiology; it does not offer an explanation, that is altogether satisfactory, of any one of the functions of the animal œconomy. Decompositions and new combinations are, no doubt, continually going forward in the living body, but they have little or no analogy, that we can trace, with the ordinary processes of chemistry. We cannot form, artificially, the simplest of the animal fluids; nor can we account, in the least, for those wonderful changes which the fluids undergo, by being subjected to the action of the secretory organs. We see the same blood carried to the liver and to the kidneys, and we find separated from it, by the action of these organs, in the one case bile, in the other urine; but neither bile nor urine are to be found in the common mass of blood, nor can we extract them from it by any art of chemistry.

Nor is chemistry of more avail in explaining the changes that take place in the body in disease. We find the condition of the fluids subject to considerable alterations under disease, but the way in which these alterations are brought about we are totally ignorant of, and equally so of the direct means of remedying them. It will enable us to destroy a prevailing acidity of the primæ viæ, and to account, indeed, for its production upon the common principles of fermentation, but it has nothing to do with that derangement of action in the organs which allows the fermentation to go on, and upon which the continuance of the disease depends. Even in calculous disorders, as the stone in the bladder, where chemistry seems to promise so much, it has, in a great measure, failed us, and we are still frequently under the necessity of resorting to a dangerous and painful operation for relief. We have, indeed, solvents which readily act upon the stone out of the body so as to dissolve it, but they are capable, at the same time, of destroying the texture of the body itself, which, in a great measure, precludes their employment.

For a long time diseases were looked upon in no other light than as chemical phenomena, and the cure of them undertaken upon corresponding principles; but the fallacy of this we are now well aware of; chemistry does not adequately explain the production of the simplest of our diseases, and consequently does not suggest any certain means of relief.

---

VACCINATION GRANT.—Mr. A. G. Bateman Lory, medical officer and public vaccinator of the Chudleigh district of the Newton Abbot union, has for the second time received the grant for successful vaccination from the Local Government Board.

Public Health and Poor Law.

LOCAL GOVERNMENT BOARD.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

Portsmouth Urban District.—Dr. A. Mearns Fraser embodies in his annual report the very lucid account which he presented to the Portsmouth town council in December last upon the prevalence of oyster-borne enteric fever in Portsmouth. This outbreak, which occurred about the same time as did the remarkable outbursts of enteric fever and other illness which followed the mayoral banquets at Winchester and Southampton, was traced to oysters procured from Emsworth, and Dr. Fraser calls attention to the fact that although the dangerous position of the Emsworth ponds was pointed out in 1896 practically no steps had since been taken to mitigate the danger. It is sincerely to be hoped, as Dr. Fraser urges, that steps will soon be taken to close not only these ponds but also all those which are obviously liable to pollution. Moreover, it is necessary that restrictive measures, albeit they are more difficult to apply than in the case of oysters, should be extended to other shell-fish such as mussels and cockles. With regard to the excessive prevalence of diarrhœa in the neighbourhood of Goldsmith-avenue Dr. Fraser makes a strong report. Although generally speaking the incidence of diarrhœa upon the town as a whole was slight as compared with certain other years there were in a circumscribed population of 817 no fewer than 102 cases (with 19 deaths) of epidemic diarrhœa. This terrible incidence is attributed by Dr. Fraser—and, indeed, by practically all the medical men who attended the cases—to the plague of flies which were attracted to the neighbourhood by the refuse collected near the brick-burning works in the vicinity. It appears that these flies are so numerous that all food has to be kept covered at meal times and that even in spite of this precaution the flies succeed in settling on the food on its way from the plate to the mouth. Dr. Fraser tells us that he found walls, pictures, and furniture covered with fly marks and that the parents were unable to prevent flies crawling into the mouth and eyes of children as they were dying The recent experiments of Firth and Horrocks have shown conclusively that both the legs and the wings of flies which have walked over media infected with disease germs may act as carriers of infection. Dr. Fraser has for several years urged upon the town council of Portsmouth the necessity for the erection of a refuse destructor and it seems difficult to understand how any sanitary authority, more particularly one of the importance of Portsmouth, should have so long delayed this provision in face of the numerous lives which have been yearly sacrificed by reason of the existing method of dealing with and utilising refuse. Dr. Fraser's scheme for the erection of a sanatorium for the county of Hampshire has not so far been successful but now that it is possible for county councils to declare pulmonary tuberculosis a notifiable disease for isolation purposes alone, and such declaration will not subject consumptive patients to all the disabilities imposed upon persons suffering from acute infectious diseases, Dr. Fraser will perhaps feel disposed to make a fresh attempt.

Metropolitan Borough of Hackney.—Dr. J. King Warry strongly deprecates the practice which largely obtains of treating cases of enteric fever at their own homes. He thinks that all cases should be isolated in hospital unless the circumstances are such as to allow of adequate accommodation and the attendance of a trained nurse. In his experience secondary cases very frequently follow when the patients are nursed at home by their untrained relatives. Dr. Warry finds that the patients frequently remain at home on the advice of their medical attendants There can, we imagine. be no question that where proper isolation accommodation and trained nursing cannot be procured the patient's chances of recovery are better at a well-administered hospital Attention is drawn by Dr. Warry to a custom which is not, we think, generally known. It is, he says, the custom of undertakers in Hackney (and inferentially elsewhere) to receive dead bodies on their premises and to keep them there until the date of the funeral. The arrangements for such storage at these improvised mortuaries are far from satisfactory and in one instance a body was even found to have been kept in the front shop adjoining the street, while in another the bodies of infants were stored in a cellar beneath the house. The abuse which a practice such as this might lead to may be gathered from the fact that in two cases the undertakers who were in possession of the bodies refused to bury them until they had been paid the cost of the funeral. The extent of the practice referred to in Hackney may be inferred from the figures of the last census, from which it appears that there are in this borough no fewer than 4827 tenements of one room only and a total of 29,087 tenements of four rooms and under. Dr. Warry thinks that even in the majority of the three- and four-room tenements the dead body is as a rule [illegible]ker, seeing that during 1902 [illegible]ken to the mortuary to await [illegible] by Dr. Warry to the dangers which attend the disposal of stillbirths. It is, he alleges, the custom for the undertakers to receive these bodies and to take charge of them until a convenient opportunity offers for their interment. This practice affords, he thinks, a favourable opportunity for the exercise of foul play, inasmuch as if the body be called a stillbirth no further inquiries are made. In Dr. Warry's opinion the law should be so altered as to provide that all dead bodies which cannot be kept at home should be removed to the mortuary and that all fœtuses which have reached the age of development of seven months should be registered upon the certificate of a medical practitioner.

Blackpool Borough.—Dr. F. J. H. Coutts, in the course of an interesting and carefully prepared annual report, refers to the danger which exists at Blackpool owing to the existence of mussels in considerable quantities on the outfall sewer itself and also upon the pier and he furnishes several instances of enteric fever cases in which the evidence suggests that the consumption of shell-fish may have caused the attack. More than this can hardly be asserted in the majority of instances. Special stress is laid by Dr. Coutts upon one case in which a policeman, nine days before the onset of the disease, procured mussels from a man who had been seen to pick them from the sewer outfall pipe. Both the policeman and one of his colleagues ate some of the mussels and on the next day the colleague was attacked by severe vomiting and purging, while the policeman referred to developed later a typical attack of enteric fever. These two cases are much on a par with those which occurred after the Southampton and Winchester mayoral banquets, when several guests suffered not only from vomiting and diarrhœa shortly after the banquet but also, later, from enteric fever. Dr. Coutts suggests as a remedy for the existing state of affairs that some satisfactory method of sewage treatment should be adopted so as to eliminate the danger of the specific infection of shell-fish. But unfortunately there is no known practical method of rendering a sewage effluent sterile *quâ* disease organisms and nothing which can be done is likely to render the safe eating of shell-fish (uncooked) which have been taken from a sewer outfall or its immediate neighbourhood.

Bristol County Borough.—Dr. D. S Davies is apparently endeavouring to introduce into Bristol that much needed reform, or rather advance, in preventive medicine which consists in the periodical examination of school children, and by way of accentuating this question he furnishes in the current annual report a summary of the practices as regards the inspection of school children which are in vogue in some English and many continental cities. There are now over 60 000 children attending the public schools of Bristol, and the periodical physical examination of these children, more especially if such examinations were followed by the cure or amelioration of defects, would make a very real impression [illegible] population of Bristol. Obviously, too, [illegible] facilitate the detection [illegible] thus would reduce the chances of school outbreaks and the necessity for closing the schools. Bristol, with its population of over 334 000 and its great wealth, might very well set an example to other large towns by initiating a really modern system of the inspection of school children and we hope that next year we may be able to chronicle this advance in the application of preventive medicine in this country. In connexion with the control of diphtheria a somewhat new departure was taken at Bristol during 1902 Those children who had been in contact with undoubted cases of diphtheria and in whose throats Hoffmann's bacillus was detected were treated as out-patients by means of antiseptic washes at the isolation hospital. After the children have been thus treated for a fortnight the throats are examined to determine if they may safely attend school. The experiment, in so far as the evidence is of value, appears to have been satisfactory. As regards the difficulty of the adequate control of milk Dr. Davies draws attention to the fact that Bristol derives its milk from 154 farms and that of this number 85 are in Gloucestershire, 67 are in Somersetshire, and two are in Wiltshire. It is, however, satisfactory in a sense to learn that only four samples out of 74 examined were found by inoculation to contain the tubercle bacillus. In the matter of the treatment of pulmonary tuberculosis the corporation of Bristol has decided to contribute £1000 towards the cost of erecting the sanatorium which is being constructed at a site near Bath for the counties of Gloucester, Somerset, and Wilts, and the corporation has also, subject to certain conditions, agreed to contribute £260 annually in order that it may have the exclusive use of four beds.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN 76 of the largest English towns 8466 births and 4573 deaths were registered during the week ending Oct. 17th. The annual rate of mortality in these towns, which had been 16·3, 15 3, and 15·8 per 1000 in the three preceding weeks, was again 15·8 per 1000 last week. In London the death-rate was 15·3 per 1000, while it averaged 16·1 in the 75 other large towns. The lowest death-rates in these towns were 3·3 in Hornsey, 7·1 in Barrow-in-Furness, 7·2 in Handsworth, 7·9 in Grimsby, 8·1 in Croydon and in Burton-on-Trent, 8·2 in King's Norton, and 9·0 in Wallasey; the highest rates were 20·2 in West Hartlepool, 20·3 in Manchester, 21·1 in Stockton-on-Tees, 21·5 in Burnley, 21·8 in Tynemouth, 22·3 in Hanley, 24·2 in Salford, and 26·3 in Middlesbrough. The 4573 deaths in these towns last week included 634 which were referred to the principal infectious diseases, against 752, 697, and 707 in the three preceding weeks; of these 634 deaths, 420 resulted from diarrhœa, 49 from "fever" (principally enteric), 45 from measles, 43 from diphtheria, 42 from whooping-cough, and 35 from scarlet fever, but not one from small-pox. No death from any of these diseases was registered last week in Hornsey, Reading, Devonport, Grimsby, Bootle, or Newport (Mon.), while they caused the highest death-rates in West Ham, Northampton, Great Yarmouth, Hanley, Smethwick, Burnley, Preston, Middlesbrough, and Merthyr Tydfil. The greatest proportional mortality from measles occurred in Stockport, Warrington, and Sunderland; from scarlet fever in Swansea; from diphtheria in Great Yarmouth; from "fever" in Walthamstow, Rhondda, and Merthyr Tydfil; and from diarrhœa in West Ham, Northampton, Hanley, Birmingham, Burnley, Preston, Middlesbrough, and Merthyr Tydfil. The mortality from whooping-cough showed no marked excess in any of the large towns and no fatal case of small-pox was registered during the week The number of small-pox cases under treatment in the Metropolitan Asylums hospitals on Saturday last, Oct. 17th, was 11, against 29, 21, and 17 on the three preceding Saturdays; one new case was admitted last week, against one, one, and two in the three preceding weeks. The number of scarlet fever patients in these hospitals and in the London Fever Hospital, which had been 1886, 1876, and 1881 at the end of the three preceding weeks, had declined again to 1860 at the end of last week; 208 new cases were admitted during the week, against 293, 235, and 240 in the three preceding weeks. The deaths referred to diseases of the respiratory organs in London, which had been 134, 161, and 146 in the three preceding weeks, rose again to 175 last week, but were 98 below the number in the corresponding period of last year. The causes of 44, or 1·0 per cent., of the deaths in the 76 large towns last week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in West Ham, Bristol, Leicester, Nottingham, Bradford, Leeds, and in 49 other smaller towns; the largest proportions of uncertified deaths were registered in Birmingham, Smethwick, Liverpool, Bootle, St. Helens, and Gateshead.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in eight of the principal Scotch towns, which had been 16 8, 17·3, and 16·0 per 1000 in the three preceding weeks, increased again to 16·1 per 1000 during the week ending Oct. 17th, and showed an excess of 0·3 per 1000 over the mean rate during the same period in the 76 large English towns. The rates in the eight Scotch towns ranged from 13·3 in Aberdeen and 13·5 in Edinburgh, to 17·7 in Glasgow and 20·1 in Perth. The 527 deaths in these towns included 35 which were referred to diarrhœa, 14 to measles, seven to whooping-cough, six to "fever," five to scarlet fever, four to diphtheria, and one to small-pox. In all, 72 deaths resulted from these principal infectious diseases last week, against 77, 65, and 71 in the three preceding weeks. These 72 deaths were equal to an annual rate of 2·2 per 1000, which corresponded with the mean rate last week from the same diseases in the 76 large English towns. The fatal cases of diarrhœa, which had been 44, 42, and 41 in the three preceding weeks, further declined last week to 35, of which 24 occurred in Glasgow, four in Aberdeen, three in Leith, and two in Dundee. The deaths from measles, which had been five, four, and eight in the three preceding weeks, further rose to 14 last week, and included 11 in Glasgow. The fatal cases of whooping-cough, which had been nine, seven, and six in the three preceding weeks, increased again last week to seven, of which six were registered in Glasgow. The deaths referred to different forms of "fever," which had been seven, six, and nine in the three preceding weeks, declined again to six last week and included two in Dundee. The fatal cases of scarlet fever, which had been two and four in the two preceding weeks, further rose last week to five, of which three occurred in Edinburgh and two in Glasgow. The deaths from diphtheria, which had been four and three in the two preceding weeks, increased again to four last week, and included two in Edinburgh. The fatal case of small-pox occurred in Glasgow. The deaths referred to diseases of the respiratory organs in these towns, which had been 84, 88, and 62 in the three preceding weeks, rose again last week to 82, but were 47 below the number in the corresponding period of last year. The causes of 24, or nearly 5 per cent., of the deaths registered in these eight towns last week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 21·7, 18·3, and 19·7 per 1000 in the three preceding weeks, declined again to 18·6 per 1000 during the week ending Oct. 17th. During the past four weeks the death-rate has averaged 19·6 per 1000, the rates during the same period being 14·8 in London and 15·8 in Edinburgh. The 135 deaths of persons belonging to Dublin registered during the week under notice showed a decline of eight from the number in the preceding week and included nine which were referred to the principal infectious diseases, against 16, five, and nine in the three preceding weeks; of these, five resulted from diarrhœa, three from "fever," and one from whooping-cough, but not any from small-pox, measles, scarlet fever, or diphtheria. These nine deaths were equal to an annual rate of 1·2 per 1000, the death-rates last week from the principal infectious diseases being 2·0 in London and 1·1 in Edinburgh. The fatal cases of diarrhœa, which had been 14, three, and four in the three preceding weeks, rose again last week to five. The deaths from "fever," which had been one, two, and one in the three preceding weeks, rose again to three last week. The 135 deaths in Dublin last week included 27 of children under one year of age and 27 of persons aged 60 years and upwards; the deaths both of infants and of elderly persons were slightly below the respective numbers recorded in the preceding week. One inquest case was registered, and 56, or more than two-fifths, of the deaths occurred in public institutions. The causes of five, or nearly 4 per cent., of the deaths registered in Dublin last week were not certified.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

THE following appointments are notified:—Surgeons: E. S. Miller to the *Tartar;* A G. Eastment to the *Impregnable;* E. S. Tuck to the *Cambrian,* for Ascension Hospital; and J. W. W. Stanton to the *Fire Queen.*

ROYAL NAVAL VOLUNTEER RESERVE.

John Macintyre to be Honorary Staff Surgeon (dated Oct. 15th, 1903). The undermentioned have been appointed Surgeons:—Peter Paterson, Alexander Laurie Brown, James Paton Boyd, and Ebenezer Snell (dated Oct. 15th, 1903).

ROYAL ARMY MEDICAL CORPS.

Lieutenant-Colonel A. T. Sloggett, C.M.G., is appointed for duty in the Home District. Captain J. C. B Statham proceeds to Woolwich for duty. Lieutenant W. F. Tyndale embarks for Bengal and Lieutenant A. B. Smallman for the Punjab early next year. Lieutenant-Colonel W. J. Macnamara is appointed Senior Medical Officer at Jersey. Colonel W. L. Chester takes over the appointment of Administrative Medical Officer, Punjab Command.

ARMY MEDICAL RESERVE OF OFFICERS.

Lieutenant J. T. K. Thomson, Glasgow Companies, Royal Army Medical Corps (Volunteers), to be Surgeon-Lieutenant (dated Oct. 14th, 1903), instead of as notified in the *Gazette* of Oct. 13th, 1903, under "Royal Army Medical Corps."

IMPERIAL YEOMANRY.

East Riding of Yorkshire: Richard Hamilton Ashwin to be Surgeon-Lieutenant (dated Oct. 17th, 1903).

QUEEN ALEXANDRA'S IMPERIAL MILITARY NURSING SERVICE.

Lady Roberts, accompanied by Lady Aileen Roberts and the matron-in-chief, Miss S J. Browne, R R C., visited the Princess Louise Hospital, Alton, recently for the purpose of presenting the badges to the ladies of the nursing staff of the hospital.

Correspondence.

"Audi alteram partem."

THE LUNG REFLEX OF ABRAMS.

To the Editors of THE LANCET.

SIRS,—In his letter on the above subject[1] Dr. A. G. Auld refers to the fact that the lungs can be made to expand—as shown by a diminution in the area of superficial cardiac dulness and a descent of their lower margins—by certain devices—e.g., by briskly rubbing the chest for a minute, by the inhalation of irritating vapours such as ammonia, by plugging the nares with cotton-wool, or finally by vigorous percussion of the epigastrium, and he assumes that the expansion in question is due to a reflex relaxation of the bronchial muscles. May I be permitted to point out that this phenomenon is susceptible of another and simpler explanation. I suggest that all the means referred to tend, independently of any influence on the bronchial muscles, to increase the mean size of the chest and thus to cause pulmonary expansion *by exciting the inspiratory muscles*; thus rubbing the chest, pummelling the epigastrium, and blocking the nares all tend by interfering with normal breathing to induce a certain amount of dyspnœa which, as I have pointed out elsewhere, excites the inspiratory muscles and thus leads to an increase in the mean size of the chest for the purpose of facilitating the circulation, notably that through the lungs, and in regard to the inhalation of ammonia there can, I think, be little doubt that it also tends to promote inspiration rather than expiration, although every now and then a violent expiration may be induced by it in the shape of sneezing.

Dr. Auld does not touch upon the interesting question how bronchial relaxation can cause expansion of the lungs in the living body. Assuming the other intrathoracic organs to remain unaltered in size, it is obvious that the lungs cannot expand without a corresponding increase in thoracic capacity. Now the primary effect of bronchial relaxation must be to cause a relaxation of pulmonary tissue and thus, by diminishing the suction action of the lungs on the thoracic walls and diaphragm, somewhat to increase the size of the chest cavity. The thoracic expansion would not, however, end here. I have in another place sought to show that throughout life the inspiratory muscles are ever busy keeping the lungs at the requisite degree of stretch so as to maintain pulmonary suction at the norm—how, e.g., it is largely in this way that the expansion of the chest in emphysema is to be explained, the inspiratory muscles coming into extra play in order to tune up, so to speak, the relaxed pulmonary fibres to the requisite pitch. The same thing doubtless happens when the bronchial muscles relax and thus tend to cause relaxation of pulmonary tissue. Any enlargement of the chest that may ensue in these circumstances is, I doubt not, chiefly brought about by the inspiratory muscles. It is noteworthy that pronounced constriction of the bronchi (sufficient to cause dyspnœa, as in asthma) also causes enlargement of the thorax; and I believe in a precisely similar manner—i.e., through the agency of the inspiratory muscles, in obedience to the law already referred to that dyspnœa favours thoracic expansion.

I am, Sirs, yours faithfully,

Wimpole-street, W., Oct. 18th, 1903. HARRY CAMPBELL.

"IMMEDIATE" AUSCULTATION AND PERCUSSION.

To the Editors of THE LANCET.

SIRS,—I read with great interest the letter on "immediate" auscultation by Sir Isambard Owen in THE LANCET of Oct. 10th, p. 1049. As one who has made use of this method largely and has demonstrated to students its value in certain circumstances again and again I may be permitted to indorse the opinion of Sir Isambard Owen as to the advisability of a "more systematic attention to the practice of direct auscultation than it obtains at present." In my case also it was by accident that I became acquainted with the value of this method. Since then I have met with many medical men who have never employed it and even with some who imagined that without a stethoscope auscultation is not feasible, whereas the fact is that not seldom the immediate is preferable to the mediate method. Very much the same thing applies to percussion. Apart from the fact that the finger is greatly preferable to any other form of pleximeter for regular use, most delicate and accurate work can be accomplished by direct percussion—i.e., by the use of one or two finger tips as a plessor without the intervention of a pleximeter of any kind. In such a case, of course, it is the sense of resistance rather than the "note" which gives the desired information. I remember a most interesting article on this method which appeared in the *Practitioner* some years ago but have forgotten the author's name. To my mind both direct percussion and direct auscultation are deserving of more attention than has been devoted to them by clinical teachers of late years.

I am, Sirs, yours faithfully,

A. E. GRANT, Major, I.M.S.

Ennore, Boscombe, Oct. 11th, 1903

MATERIA MEDICA AND THE MODERN CURRICULUM.

To the Editors of THE LANCET.

SIRS,—I was privileged to hear the address which Professor Schafer delivered at the Yorkshire College, Leeds, on Oct. 1st and in the main consider that his very practical suggestions ought to be of great value to the authorities of the forthcoming new university in framing their medical curriculum. I would like, however, to draw attention to his remarks concerning materia medica, and with this I presume is included practical pharmacy. He says, "Materia medica in the strict sense ought not to be part of the curriculum."

Now there seems to be a growing tendency in all our medical schools to minimise the value of these subjects in forming a part of medical education, and hence no wonder that so many men receive diplomas and degrees to practise medicine and surgery who possess the barest possible knowledge of the simplest drugs. I am well aware, of course, that in degree of importance the subjects of physiology, pathology, anatomy, &c., should take priority, but I am confident it would be a retrograde step to remove materia medica from the curriculum.

My point is this, that inasmuch as probably nine-tenths of [illegible] to-day dispense their [illegible] public *and to the profession* that they should be properly trained to do so during their curriculum. This seems to me, again, the more necessary since the old apprenticeship days are gone, for now many men may qualify without much practical acquaintance with the British Pharmacopœia and a very limited theoretical acquaintance also, a circumstance which they always afterwards regret.

---

[1] THE LANCET, Oct. 17th, 1903, p. 1118.

It may be argued that materia medica and practical pharmacy are the province of the qualified pharmacist. Granted this to be the case, speaking on the lines of perfection, but we nevertheless have to deal with what *is*, and so long as the great bulk of general practitioners continue to do their own dispensing I submit that the medical schools ought not to relax their teaching in these subjects in the way which is so evident on all sides.

Professor Schäfer goes on to say: "A scientific acquaintance with the action of drugs under both normal and abnormal conditions is quite another story and pharmacology must in future have its due position in the medical curriculum." The student, then, is to know all about the action and uses of drugs without necessarily being acquainted with their physical characters. This savours very much to my mind of mechanical empiricism. I prefer the workman who not only knows how to *use* his tools but knows all about the tools he is using.

In conclusion, let me say that in my opinion this inefficient knowledge of materia medica and pharmacy on the part of many members of our profession is very largely responsible for the reprehensible practice now so prevalent of prescribing and recommending so many proprietary nostrums. If the B.P. is not q.s. along with an addendum, say, such as Martindale's, it *ought* to be, and it becomes a serious reflection on the Pharmacopœia Committee if it be not kept up to date. But this modern practice of prescribing So-and-so's liquid extract and So-and-so's "oids"—very often merely as the result of an interview with an eloquent commercial traveller—is the outcome and the evidence of a most deplorable ignorance which should not prevail.

I am, Sirs, yours faithfully,
Horbury, Wakefield, Oct. 10th, 1903. WALTER ASTEN.

THE VISION OF MYOPES.

To the Editors of THE LANCET.

SIRS,—The fact recorded by Mr. E. Donaldson in his interesting letter in THE LANCET of Oct. 17th, p. 1118, that vision can be improved in a myopic eye by drawing upon the outer canthus with the finger especially appeals to me as being in accord with a theory I propounded some years ago that the external ocular muscles were coördinates that had to be taken into account in considering the so-called static refraction of the eye (vide *Ophthalmic Review*, 1900, p. 211). In that article I mentioned that a myope's sight could usually be improved for the time being by pressing the globe backwards with the finger through the upper lid. I made use of the fact to support some heretical views with regard to polar pressure mechanically making the eye less myopic. Mr. Donaldson's method would have the same effect on the globe and he gives the orthodox explanation that dragging on the outer canthus enables the lid to cut off the diffusion circles, but may it not be that the dragging also causes pressure on the eye, the result of which is that it is somewhat flattened? I do not deny that a diaphragm renders objects clearer by cutting off diffusion circles but in the instance in question I think the fact that dragging the canthus outwards causes diplopia (an observation which can easily be tested) shows that pressure is exerted on the eye.

I am, Sirs, yours faithfully,
Bath, Oct. 18th, 1903. W. M. BEAUMONT.

THE HATCHING OF CHICKENS FROM PRESERVED EGGS.

To the Editors of THE LANCET.

SIRS,—In an annotation on the above subject which appeared in THE LANCET of May 16th, 1903, p. 1393, reference was made to a statement that chickens had been hatched out from eggs which had been preserved for 12 months by immersion in a 10 per cent. solution of sodium silicate. The result indicated seemed so remarkable as to make it worth while to repeat the experiment. Some friends of mine kindly undertook to carry out the following experiment. Twelve eggs were collected in June and immediately placed in a 10 per cent. solution of sodium silicate and completely covered by the solution. On Sept. 5th four eggs were taken from the solution and marked and with nine other newly laid eggs were placed under a hen. All the newly laid eggs hatched out within three weeks but the four preserved eggs did not hatch. One of these eggs was boiled and was quite fresh; the other three were broken and the yelk fell out separately from the white. The whites were whipped up and became quite stiff. This is stated to be the best test of a fresh egg. It is of interest to note that these preserved eggs, even when they had been incubated for three weeks, still remained perfectly fresh, seeming to indicate that the shells were still impermeable to external influences.

Assuming that the remarkable preserving effect of the sodium silicate is due to the formation of an insoluble glass with the lime salts of the substance of the shell it is curious that it has been possible to hatch out a chicken without first making the shell again permeable to air. The experiment is one which should be repeated after the shell has by some method again been rendered permeable, for it seems improbable that the hatching of such preserved eggs can take place if the shell remains impermeable to air.

I am, Sir, yours faithfully,
Oct. 20th, 1903. FREDERICK E. BATTEN.

THE M.D. DEGREE OF BRUSSELS.

To the Editors of THE LANCET.

SIRS,—Dr. P. A. Nightingale states in THE LANCET of Oct. 17th, p. 1119, that the M.D. Brux. confers no right to practise in Belgium and, secondly, that the Belgians take the "State degree" which, in the words of Dr. Nightingale, is "quite another matter." While in Brussels I made inquiries on both these points and was assured that the degree *does* confer the right of practising there after certain legal formalities are gone through and this is evidenced by the fact that two or three Englishmen are now practising there. Moreover, I was given to understand that the examination for foreign candidates is identical in every respect with that of the Belgian students.

I am, Sirs, yours faithfully,
Westcliff-on-Sea, Oct. 18th, 1903. N. LEONARD.

THE MEDICAL REGISTER.

To the Editors of THE LANCET.

SIRS,—I beg to thank you for your courtesy in complying with my request to draw the attention of members of the profession to the importance of accuracy of address. We have had about 300 communications in the past three days and five persons whose names would have been erased at the end of the year under the operation of Section XIV. have saved themselves, so that the result may be considered very satisfactory.

I am, Sirs, yours faithfully,
H. E. ALLEN,
Oxford-street, W., Oct. 14th, 1903. Registrar.

A BIOLOGICAL THEORY OF THE ORIGIN OF NEOPLASMS.

To the Editors of THE LANCET.

SIRS,—As the study of the origins of neoplasms is commanding a great deal of attention at present, I would like to suggest a natural origin for these tumours. I think rather too much attention has been paid to the heredity of the entire organism and too little to the special hereditary tendencies of the cells themselves which enter into the growth. In the endeavour to obtain an idea of these hereditary properties we must necessarily start at the period when all organisms were in the unicellular state; then study the causes that lead to increased proliferation of cells—first, in the protozoa of unicellular type, and, secondly, in the multicellular organisations where the daughter cells do not separate from the parent except to form the foundation of a new colony. In the unicellular group we find that when the normal cell has not sufficient excess of vitality left to continue reproduction by dividing it resorts to coalescence with another cell and from the stimulation derived there results a great output of daughter cells. In the multicellular organisms of a primitive kind we find that although there is already an attempt made to limit the reproductive functions to certain cells, still that the ordinary tissue cells can take on this function and do.

Remembering the above facts, on looking at that great multicellular organism the human body, we find that certain cells are set apart for the reproductive functions and the majority of cells are the tissue elements as in [illegible] organism: should we not expect that at least occa[illegible] an atavism favoured by certain circumstances [illegible] tissue should take on the reproductive function, [illegible] *union of two tissue cells* originate that greatly increased cell proliferation which is a neoplasm. This growth would take on the type of the tissue in which it originated.

And what are the causes likely to favour this reversion of a *specialised cell to the habits of its remote ancestors?* Any cause which renders the cell less specialised in structure, more motile, or more devitalised when a call is made for exertion to proliferate and repair.

Such a cause is found in long-continued irritation causing frequent destruction of tissue The ordinary tissue cells are at first quite capable of dividing to repair the gap without resorting to extraordinary means. But when the destruction of the newly laid down tissue is repeated time after time there arrives a period at last when the cells have grown feebler and feebler and give off more and more stunted and primitively developed daughter cells. They require more stimulus and they resort to the only other means in their cellular history of meeting with the demand—viz., two of them unite and then succeeds the tumour. And it is probable that this happens at the same time to several cells which have suffered equally long from the same strain.

I would point out, in conclusion, that by the coalescence of cells of various kinds at the same time, but each two breeding true to kind, we get a good explanation of mixed tumours, and that looking at the history of cells it should be evident to any evolutionist that there must be atavistic reversions of ordinary cells to the reproductive functions which all cells once shared.

I am, Sirs, yours faithfully,
NIEL FLETCHER MACHARDY, M.B., Ch.B. Edin.

RELAPSES IN SCARLET FEVER.

To the Editors of THE LANCET.

SIRS,—I should be glad if you would allow me through your valuable paper to ask those who are connected with fever hospitals as to whether they have had any cases similar to those which I now describe. 1. Four months ago I admitted to the Brentford Fever Hospital a young girl, nine years of age, with a very severe attack of scarlet fever. She peeled freely and was discharged in the usual course of events. To-day, two months after her discharge, I have readmitted her suffering from a very severe attack of scarlet fever, both rash and throat being characteristic. 2 I admitted two cases of severe scarlet fever in the early part of the year; during the peeling stage, which was very profuse, they were both taken with rigors, sore-throat, and a fresh rash, just as if they had never had scarlet fever before. 3 Some three years ago I discharged a child who had peeled freely from scarlet fever and had been two months in the hospital. Within a fortnight she was readmitted with a well-developed rash and sore-throat and peeled again all over freely. I have been connected with this fever hospital for some 15 years and have seen some hundreds of cases of scarlet fever, and I must confess that these cases puzzle me very much. I should be glad to know if a similar experience is common at other fever hospitals and, if so, what is the explanation of these cases?

I am, Sirs, yours faithfully,
Brentford, Oct. 13th, 1903. CHARLES DIXSON, M.D. Durh.

A MINISTER OF PUBLIC HEALTH.

To the Editors of THE LANCET.

SIRS,—I have recently had the honour of presenting a communication to the International Congress of Hygiene on the need for Ministries of Public Health and in consequence I beg to be allowed to make certain suggestions. Briefly, I believe the formation of a Health Ministry to be necessary to national prosperity if the latter is to be based on a sound foundation. It is more important than fiscal reform, than War Office reorganisation, than very many matters that fill the lay press day by day, but public opinion is insufficiently aroused and educated at present. How to create a popular "vote" in the interests of health is the work of those associations and congresses that are considering, or have considered, the matter. The British Medical Association, the Sanitary Institute, the Royal Institute of Public Health, the Imperial Vaccination League, the housing associations, [illegible] ssociation, the Madrid Society, the proposed [illegible] many eminent medical [illegible] forces at no distant date. Above all, the British Medical Association could influence representatives of the governing bodies through its branches over the British world to form an Imperial Ministry of Public Health somewhat as in Germany.

In order to raise the matter above party or sect and to place it on the level of international well-being and amity it is necessary to approach the English and foreign members of the international committees of future congresses of hygiene and medicine and to obtain an official recognition of the subject on the programme The views of eminent men of all countries could be obtained thereby, sound conclusions arrived at, and action taken. I do not think it is necesary to labour the point as to the need for a strong State Health Department. Mr. Balfour's recent words applied to the Macedonian trouble appear very applicable, however, at home, where charity is said to begin—viz., a "policy of humanity" is the "policy of wisdom."

Hitherto the evolution of public health progress has followed panic consequent on outbreaks of epidemic diseases such as cholera, small-pox, &c. This should be replaced in the name of common sense and in accordance with our own interests by the continuous and consistent educational efforts of a Ministry. The amount and exercise of the authority that such an expert Minister should possess may be suggested by the opinions of Lord Rosebery in the matter of the War Office, whose expert chief should have important relations to the Cabinet.

I am, Sirs, yours faithfully,
Plymouth, Oct. 15th, 1903. F. BUSHNELL.

*** We have already referred to the subject in an annotation which appeared in our issue of Oct. 10th, p. 1028.—ED. L.

SECONDARY HÆMORRHAGE AFTER ENUCLEATION OF THE EYE-BALL.

To the Editors of THE LANCET.

SIRS,—Referring to the case under the care of Sir William J. Collins which was recorded in THE LANCET of Oct. 3rd, p. 958, I had a *similar experience of persistent* hæmorrhage (following Mules's operation) several years ago in a patient with hæmophilia which quickly yielded to plugging the orbit with pledgets soaked in perchloride of iron which he does not appear to have tried. From his case it would seem that ancient as well as modern treatment is still of value and worth a trial. For in these days of rapidly increasing new drugs, &c., I fear that we all have a tendency to dispose of much valuable treatment as obsolete.

I am, Sirs, yours faithfully,
W. O ROCKLIFFE, M.A. Cantab, M.D. Dub.,
Honorary Ophthalmic Surgeon, Hull Royal Infirmary.
Oct. 19th, 1903.

NOTES FROM INDIA.

(FROM OUR SPECIAL CORRESPONDENT.)

The Traffic in Sores.—The Slow Progress of Sanitation in India.—The Plague Epidemic.

THE nuisance of beggars in India is intensified by the numbers of leprous and diseased cripples who haunt the thoroughfares of most towns. In Bombay it is complained that they stand in rows endeavouring to excite the compassion of passers-by. The sight is not only offensive but revolting and there is probably danger in allowing so many lepers to move about and to live in the most densely populated quarters of the town. The very worst cases and the most contagious are the most in evidence. In Calcutta this traffic in sores is also a serious and constant evil. There is a growing opinion that the time has come for these pitiable mortals to be prevented from turning their misfortunes to account in earning a livelihood to the nuisance and danger of the public and that adequate provision will have to be made to keep them out of the way.

[illegible] of the [illegible] on [illegible] les [illegible] (about £1082) were spent in [illegible] sanitary matters other than water-supply and drainage and the report says that beyond improvement of the water-supply by constructing, repairing, and improving wells and disinfecting them no important works of sanitation were undertaken by the several district boards during the year, though the usual arrangements were made for the sanitation of fairs. It appears that the boards have money allotted to them for the improvement of tanks (as sources of water-supply), but in many cases they could not expend the money because, forsooth, the zemindars who own them were unwilling either to excavate them themselves for the benefit of their tenants or to make them over to the boards. This is the old story. These native landlords draw their steady incomes in the way of rent from the poor peasants (the peasants in nearly all cases owning their own huts) but they will not expend a farthing of it for the benefit of those tenants. Sanitary improvements will never be effected without some form of compulsion.

Since I last reported there has been a great increase in the mortality from plague throughout India. Last week's figures gave a total of 13,996 deaths which compares very unfavourably with 8821 for the corresponding week of last year. The usual autumnal revival has set in with even greater virulence than ever. Bombay Presidency reports 9163 deaths, Bombay city 73, Central India 1712, Berar 745, Mysore State 673, Central Provinces 340, Punjab 83, United Provinces 70, Bengal 39, and Calcutta 27. There have been slight decreases in the Madras Presidency and Hyderabad State. The cities of Allahabad, Cawnpore, and Meerut are all involved by a sudden infection. In Mhow the outbreak continues to be very virulent. Here there has been a real effort made to effect permanent sanitary improvement—viz., by condemning some 150 houses in the most crowded parts of the bazaars. Over 100 deaths a day have been reported and up to Sept. 19th 3744 deaths have been recorded. A small amount of inoculation has been practised with satisfactory results. Of 1200 persons inoculated 12 only contracted plague and there was only one death. The Lucknow people complain that so little is done to combat the plague epidemic. Last year the city had 4000 deaths and 20,000 people fled away. The municipality declines to adopt measures for the extermination of rats and it is thought that the Government is too much inclined to consult native opinion by which the plague officers are deprived of moral support. A serious consequence of plague measures has shown itself in the Punjab during the past year in the increased number of burglaries and offences against property, especially in evacuated houses. This has consequently acted against this salutary measure; the public fearing the loss of their property. With the abandonment of inoculation and the stoppage of the only other successful measure against plague the prospects for the ensuing season are black indeed.

Oct. 3rd.

POST-GRADUATE WORK ABROAD.

IV. BUDAPEST.[1]

(By a Special Correspondent.)

The object of the present article is to call attention to the excellent facilities for post-graduate instruction which may be obtained in Budapest, especially for workers along the special lines to be more fully described below. This city, the capital of Hungary, is four hours distant from Vienna by express train and has a population of over 500,000 people. The hospitals, of which the three larger ones contain over 2300 beds, draw their patients from an unusually extensive area of surrounding country and are consequently well supplied with clinical material. In addition to these general hospitals perhaps the most important teaching centre is the central "Kliniken" which is in reality made up of a number of buildings devoted to the special branches. These central clinics contain from 800 to 900 beds and all branches of medicine are here represented. Special mention may be made of the new surgical section and the new gynæcological section in connexion with these clinics, since they embody all the latest ideas on the subject of hospital construction and are admirably equipped. The physicians and surgeons in charge of these clinics—the more specialised departments of which will be outlined below—are very cordial in the reception accorded to visiting colleagues and offer them many of the facilities enjoyed by themselves. For those who have had especial training in gynæcology and obstetrics, pathology, and diseases of the ear, nose, and throat, Budapest has great attractions, mainly because of the fact that these particular fields are not overcrowded with seekers after knowledge, that visiting colleagues are always welcome, and also that along the lines last mentioned the actual work may be done by the worker himself. Similar facilities can, of course, be secured in other cities on the continent, notably in Vienna, but the ever-present difficulty attendant upon the overcrowding of the field to the detriment of the advanced workers who may contemplate a sojourn on the continent purely for the purpose of "doing the work himself" will be found, perhaps, less evident in Budapest than anywhere else. With regard to language, Hungarian, of course, predominates, but without exception all the medical men in charge of clinics speak German and many of them French and English as well.

Pathology.—Special mention must be made of the excellent pathological institute in connexion with the central clinics above mentioned which is undoubtedly one of the best equipped laboratories in Europe and which was erected some years ago at a cost of £50,000. The necropsies made in this particular institute number over 1000 yearly and ample opportunity is given to workers in pathology of carrying out the examinations themselves. Visitors are most cordially welcomed by the director, Professor Pertik, and every facility and encouragement are given by him to those who desire to undertake particular lines of research. A special working table is allotted to those who contemplate making a prolonged stay and the large stock of museum specimens which have been accumulated during the last nine years, together with an excellently arranged collection of over 10,000 microscopical sections, are freely placed at their disposal. The system of recording the daily observations made in the post-mortem room is an especially good one and the reports of the last 8000 or 9000 cases, arranged in a manner easy for reference, will be found a valuable aid to workers along the statistical lines of research. Professor Pertik's demonstrations during the semester are particularly good from the teaching standpoint, since microscopical preparations of the macroscopic material to be demonstrated are fully described and the mechanism of death is carefully considered.

Gynæcology and obstetrics.—The Universitats Frauen-Klinik—the gynæcological section of the central clinics—the old Semmelweiss clinic—is in charge of Professor Barsony. This clinic is new and very well equipped in accordance with modern ideas; it contains 100 beds for obstetric cases and 40 beds for gynæcological cases. The last yearly report showed that there were 1542 births with two maternal deaths, while in the gynæcological department 298 in-patients were treated, with five deaths. There are 3000 out-patients yearly attending this clinic.

The finest special hospital in Budapest, and perhaps even in Europe, with a possible exception in favour of the recently opened hospital in Dresden, is the new building devoted to gynæcology and obstetrics, which, however, is not connected with the central clinics so far described. This hospital is in charge of Professor Tauffer, formerly first assistant to Professor Hegar in Freiburg, and contains 120 beds. The service here is a large one, consisting of about 2500 in-patients and out-patients yearly in gynæcology, together with about 1000 in-patient and 1500 out-patient midwifery cases yearly. Service in this hospital is offered as follows: first month as interne in obstetric service; second month on out-patient obstetric service; and third month as interne on gynæcological service. This, of course, implies living in the hospital and carries with it a small monthly fee paid to the incumbents.

Surgery.—The opportunities open to post-graduate guests for doing operative work are necessarily few. (In this connexion the word guest is to be taken literally, differing markedly in this respect from many of the other centres of instruction in Europe, since the so-called "private courses" common to Vienna and Berlin, in which a small class is made to cover the ground under an assistant, are made remuneratively worth the assistant's time.) These opportunities will, however, probably be found less difficult to obtain here than elsewhere for those who will be able to spend a few months in the service either of the surgical section of the central clinics or in one of the many hospitals.

---

[1] No. I. (Paris), No. II. (Berlin), and No. III. (Vienna) were published in The Lancet of Sept. 12th (p. 781), Sept. 26th (p. 912), and Oct. 17th (p. 1121), 1903, respectively.

Guests will be appointed "externists" which implies actual service in the dispensary and after about two months of such [illegible] operative cases. Professor [illegible] are in charge of the surgical [illegible] This section contains 180 beds; 1400 in-patients are treated yearly and there are from 800 to 900 operations yearly. The dispensary service is divided as follows: (1) general surgery, 5000 patients; (2) orthopædic, 2000 patients; and (3) genito-urinary, 1000 patients. Professor Navratil is in charge of the surgical work in St. Rocus Spital. This contains 100 beds. The in-patients number 1500 yearly, while the dispensary service numbers 11,000 during the same period.

Laryngology and rhinology.—In this department work may be secured in the clinics of Professor Irsai, Professor Onody, and Professor Navratil. For those who wish to study tuberculosis of the larynx the clinic of Professor Irsai may be especially recommended as it is particularly rich in material of this description and Professor Irsai is exceptionally liberal in apportioning operations. The daily average of patients is from 60 to 70. The clinic of Professor Onody is to be recommended for the study of the affections of the nose and the accessory sinuses. (His researches along the lines of the anatomy of the sinuses in recent years make his clinic an especially interesting one from this point of view.) The material here, however, is somewhat less than in the one mentioned above. Professor Navratil occupies the chair formerly held by Czermak who in the early days of laryngology did, perhaps, more than anyone else to advance the science. Attached to the clinic are 24 beds and the yearly number of in-patients is about 550. The dispensary service averages over 3000 patients yearly.

It is not intended that this short article should convey the idea that at last the Mecca for post-graduate work has been found. I merely wish to imply that for a certain class of workers in gynæcology and obstetrics, in pathology, and in diseases of the nose and throat, Budapest will be found an ideal post-graduate school. Such workers need not content themselves with being mere onlookers but may assist the operator or in certain circumstances may do the work themselves. There must be many who would desire to do their post-graduate work under such conditions and to them I cordially recommend a trial of Budapest.

BIRMINGHAM.

(FROM OUR OWN CORRESPONDENT.)

The Housing Problem.

AT the recent Worcester Diocesan Conference this subject was matter for a lengthy discussion, a motion, which I had previously communicated to you, having been brought forward by Dr. A. H. Carter who pointed out that whilst the difficulty in London was a want of houses that in Birmingham was of a different nature. The last report of the housing committee had shown that there were 785 houses to be let at rentals of 4s per week. Back-to-back houses were the chief evils in Birmingham, where there were some 42,000 of them. Undoubtedly thousands of our fellow men and women were living under [illegible] ble with physical [illegible] ter also defended [illegible] hich has come in [illegible] ere never was a [illegible] were displaying more energy or had a stronger grip of the problems which the housing question involved and were engaged in work which was more likely to be crowned with success than at the present time. The committee's plan was to make the best of existing property. It was opening up courts, pulling down houses so that courts previously inclosed opened up to the street, and seeing that dwellings were put in proper repair. This work was done at surprisingly small cost and he thought that the citizens should be grateful to the civic authorities for the work which they were doing. An extremely interesting report has been issued by the housing committee for the consideration of the council at its next meeting. It is based upon the evidence which has been obtained during the past 12 months from persons engaged in philanthropic work and others and is thus a very valuable contribution to the literature of a question which has recently assumed such great importance. According to this report the reasons for the existence of so many unsatisfactory houses in Birmingham are that in past times many houses were erected in such a way as to be unfit for habitation according to modern ideas of sanitation. For a number of years the corporation refrained from doing more than ordering minor repairs for fear of increasing the overcrowding in the other houses if extensive pulling down was resorted to. The history of the Birmingham improvement scheme shows that this fear was baseless, for the destruction of 478 houses at that time did not lead to the results which might have been feared. Many of the unfit houses are occupied by persons of drunken and dissolute habits; indeed, the condition of the houses is often due to the tenants themselves. On the other hand, the evidence shows that there are a large number of persons living in cheap houses who could, and would, pay a higher rent if they could get a better class of house. At the same time, there is a proportion whose circumstances will not permit of their paying more than 3s. or 4s. per week in rent, who are respectable in spite of their poverty, and who keep their houses clean and tidy. It had also been shown by the evidence collected that for some years very few houses have been built to let for less than 5s. 6d. per week. The reasons for this are that land has largely increased in value, wages in the building trade have gone up from 20 to 30 per cent. during the last 20 years, and materials have risen considerably in price. The rates are higher and the building laws are much more stringent. Moreover, the average working man requires better accommodation than he used to do. There has been a considerable exodus from the centre to the outskirts of the city, where many industries have been established of late years. The housing committee declares that it desires to do all in its power to encourage a high standard of living and the exodus above spoken of. The committee does not recommend a policy of municipal house building and gives the following as its reasons: 1. Experience shows that in spite of the fact that corporations can borrow money cheaply municipal house building is more expensive than any other. 2. Municipal houses if let at a lower rent than those around must be let at a loss. This means that one class of ratepayers is paying part of the rent of another. 3. The evidence shows that rate-aided competition in house building and letting will drive everyone else out of the field, with the result that the supply will not meet the demand and a house famine will ensue. As a matter of fact, since the council decided to hold its hand in the matter of house building schemes for the erection of flats at rentals of from 3s to 6s. 3d. per week have been started by two different persons. 4. It is urged that the community ought to provide good cheap houses for the respectable poor. But these are just the people who will not come forward for such houses: they will have to be sought for. Meantime, the applications of those who present themselves would have to be scrutinised in an inquisitorial manner impossible for a public body. And supposing such an inquiry were carried out, those just above the limit for admission to a cheap house would suffer a great injustice and would be tempted to earn lower wages, by doing less work, in order to qualify for the better and cheaper house. 5. Municipal house building is a form of rate-aided charity to the poorest inhabitants which must press heavily upon those ratepayers above that limit but who already find it difficult to make both ends meet. 6. The only effect of municipal house building, supposing it to reduce rent all over the city, would be to benefit employers of labour, since it is a well-known fact that wages follow rent. The committee recommends: 1. That every house in the city which is unfit for human habitation should be made fit as soon as possible and that the corporation should do what it can to encourage, and if necessary to compel, the landlords and tenants to keep their houses clean and in good order. 2. That congested courts should be opened to the streets, cleared of all obstructions, and the out-buildings rearranged so that a proper amount of light and air is admitted to every house that remains. 3. That open spaces should be provided in the city wherever possible for the rest and recreation of the people. 4. If, and when, the above proposals create a scarcity of good, cheap houses, then, and not till then, should the corporation contemplate a scheme of municipal house-building. 5. Some of the by-laws have been modified so as to decrease the cost of building without at the same time interfering with the sanitary condition of the houses. It should be considered whether more might not be done in this direction. 6. Miss Octavia

Hill's system of rent collecting, which has been so successful in other places, should be started without further delay in Birmingham. 7. The installation of an up-to-date and complete system of trams in the city itself and cheap through means of communication between the city and its suburbs, so that working men who have to earn their living in the city may be able to live in the country where land is cheap and the air fresh, is strongly to be insisted upon. If this policy is vigorously and prudently followed for the next few years it will, in the opinion of the committee, enable and encourage the poorer section of the community to live in more comfortable and sanitary surroundings. A copy of the evidence given by the numerous witnesses is appended to the report in question.

Medical Practitioners' Union.

The annual meeting of the Birmingham and District General Medical Practitioners' Union recently held, together with the report of the council presented at that meeting, shows that the affairs of the society are in a flourishing condition. The membership is now 281, that being an increase of 31 on the numbers for the previous year, and the treasurer's balance-sheet shows a substantial sum on the right side. The report calls attention to the fact that a code of ethics has been drawn up during the year and circulated. Of this code I have already given an account in your columns as well as of the action of the union in connexion with the notification of cases of chicken-pox.[1] A series of regulations dealing with club practice have been drawn up by the executive committee and are to be circulated amongst the branches for criticism. The union has now secured for itself a position of strength which has never previously been attained by any similar organisation in the city and is perhaps the more needed because the branch of the profession whose interests it has at heart is so singularly in the minority on the ruling bodies of the Birmingham branch and the Birmingham division of the British Medical Association. The six representatives on the branch council from the central (Birmingham) division consist of five consultants and but one general practitioner, whilst of the 15 members of the executive committee of this division 11 are consultants. Considering that general practitioners are to consultants at least as five is to one this division seems a curious one and has been much commented on.

MANCHESTER.

(FROM OUR OWN CORRESPONDENT.)

Dangers from Sewer Gases.

THE city coroner, Mr. E A. Gibson, held an inquest on Oct. 14th as to the death of a labourer named Foley employed at some chemical works at Clayton, Manchester. He was working at the foot of a well about 14 feet deep when he was overcome by a rush of gas, was drawn up from the well in an unconscious state, and died before a medical man arrived. A witness said that Foley collapsed as he was descending the ladder and that he himself was overcome when going down to bring him up. Another man tried to reach Foley but the fumes drove him back. The medical evidence was that death was caused by asphyxiation. After Foley was drawn up one witness noticed a smell of sulphuretted hydrogen. One of the corporation river inspectors said that he had investigated the matter and after he had taken a rod from one of the six-inch drains there was a rush of greenish liquid containing sulphuretted hydrogen and carbon dioxide. He said that the liquid which went into the drain was not the result of any process of manufacture, "it was drainage from a sump heap." Such a mixture as went into the sewer would give off noxious gases. "The lesson he drew from the occurrence was that the danger could be stopped." He did not think that there was negligence but with their present knowledge the firm should be expected to make the conditions different. "The presence of the gas in the well could not have been foreseen." Dr. Fowler, chemist to the rivers department of the corporation, agreed with this evidence and said that in the course of the investigations more than 600 samples had been taken from the well and drains. The coroner said that "it was clear that there was 'carbonite' in this drain and that, coming in contact with the acid, it had created carbon dioxide gas." Whatever the chemical changes may have been a deadly gas was produced. "The jury could not come to the conclusion that there was anyone to blame so far as the use of the sewer was concerned." The verdict was "Death by misadventure." These deaths from sewer gases, occurring as they do in Manchester too frequently, are greatly to be deplored, for they ought to be guarded against. This was evidently felt by the jury, "who added a recommendation that the corporation should make use of their powers to keep noxious vapours out of the drains and sewers." They also very properly "strongly urged that where wells of this description were used proper appliances should be at hand and that ropes should always be used." These are self-evident precautions which ought not to require enforcing by a coroner's jury and something might surely be done to drive off noxious gases before the descent of workmen.

River Pollution: a Good Word for Salford.

The action of the Mersey and Irwell joint committee against the Salford corporation again came before Judge Parry on Oct. 14th. Mr. Strachan, an expert as to sewage purification, presented some time since a report of what was needed which was adopted by the Salford council, which had practically undertaken to carry out Mr. Strachan's plans. It seems that two pumps are at work and a third is to be erected within the next six months when there will be three at work each capable of pumping 14,000,000 gallons a day. At present the pumping power is inadequate. Judge Parry said his view was that the corporation had done extremely well in this matter now. "As they had put forward this scheme in what he thought a most statesmanlike spirit he supposed the joint committee would try to assist them," which was promised on behalf of the committee. An extension of time was given to the corporation till Oct. 14th, 1904.

Music Licences and Sanitation.

On Oct. 12th some of the applications for music licences were heard before the Manchester justices which had been adjourned either on sanitary grounds or because the premises were unsuitable or for other reasons. The applications were chiefly by beer-sellers and some people may be surprised to hear of the size of the rooms in which it was intended that the charms of music should intensify that of beer drinking. Licences were wanted for rooms 12 or 13 feet by 10 or 11 feet. One beer-seller said that a music licence had been attached to his house for 40 years and entertainments had been given all that time in a place 12 feet 9 inches by 10 feet 9 inches. "Paid talent" was employed, for he had a pianist and a "chairman" and a gramophone. In another case the applicant employed "a blind young lady" as pianist in a room 18 feet by 11 feet. One man wanted his licence renewed for a room like a long passage 29 feet 6 inches by 7 feet 10 inches but the magistrates would not have concerts in passages. This case was adjourned for the production of plans. In several cases the concert rooms could not be reached except through bars or private living rooms and sometimes they were so placed as to be inaccessible to police supervision or there was no retiring accommodation apart from that of the family. One can imagine the pestilential state of the air of many of these rooms crowded with the unwashed in their unwashed clothing, well filled with the smell of beer, and obscured with the fog of tobacco smoke. A considerable number of the applications were refused.

Dr. C. J. Cullingworth on Charles White.

An interesting meeting of the Manchester Medical Society was held in Owens College on Oct. 7th, Dr. A. M. Edge, the President, being in the chair. Dr. Cullingworth delivered an address upon Charles White. The address, the major portion of which appeared in THE LANCET of Oct. 17th, p. 1071, was followed with the greatest attention and interest.

Oct. 20th.

SCOTLAND.

(FROM OUR OWN CORRESPONDENT.)

The Winter Medical Session in Edinburgh.

THE middle of October brings with it the end of the holiday season in Edinburgh and the medical classes have been opened by the various lecturers in the usual undemonstrative fashion. The most important change in the University is the transference of the teaching of anatomy from the veteran teacher Sir William Turner to his distinguished former pupil Professor D. J. Cunningham. In the pathological department an enlarged and greatly [illegible] has been provided by an [illegible] will remember that the [illegible] University new buildings was a very lofty one. By taking some feet off the unnecessary height of the practical class room and adding them to the space under the slates without removing the roof excellent accommodation for the bacteriological department was obtained. This has been done with Carnegie Trust money. The number of students attending this special subject has largely increased and it is said that this result is due to students availing themselves of the Carnegie funds for taking extra classes. It might be well to mention here that students may have their fees paid for extra-mural as well as for University classes, provided that they are studying for a University degree. The Carnegie Trust is also interesting itself in the extra-mural school and in the Medical College for Women. It has indicated its willingness to consider applications for [illegible] purposes and these are at [illegible] view to arrangements being [illegible] the Carnegie trustees. A further development on the part of the trust is that it has taken over the Royal Colleges laboratory on certain conditions. The building has been purchased from the Royal College of Physicians by the trust but the laboratory work is directed by a committee in which the College has the larger number of voices. Another matter of interest which coincides with the opening of the winter session is the opening of the new City Hospital for Infectious Diseases at Colinton Mains. Last week it was thrown open on one day for inspection by the members of the medical profession and on several other days to the general public.

---

[1] THE LANCET, May 2nd, 1903, pp. 1270-71.

Imported Enteric Fever at Glasgow.

In THE LANCET of Sept. 19th, p. 852, reference was made to a series of cases of enteric fever which had occurred in Glasgow and which were due to the eating of shell-fish. The bacteriological examination undertaken by Dr. R. M. Buchanan, the city bacteriologist, has now been completed. He reports as follows. The circumstances attending the recent outbreak of typhoid fever amongst the holiday visitors from Glasgow and other places to one of our west coast towns in the latter part of July pointed to shell-fish as the most probable source of the infection. In each case it appeared that shell-fish had been eaten raw or partially cooked and that symptoms of typhoid fever ensued after the lapse of the usual incubation period of about a fortnight. The shell-fish were gathered by the visitors themselves from an area of foreshore constantly polluted by the sewage of the town and of two large public institutions. The shell-fish examined were collected within the sewage-polluted area and also at some distance therefrom where shell-fish are gathered for market. All the varieties of shell-fish (cockles, mussels, winkles, and "muscin") from the sewage-polluted area bore evidence in almost every specimen examined of the presence of a bacillus of excremental origin—namely, the bacillus coli, a bacillus the natural habitat of which is the intestine and the presence of which is an accepted indication of sewage contamination. Cultures of this bacillus were found to have a high degree of virulence, killing guinea-pigs within 18 hours. On the other hand, the shell-fish obtained at a distance of from one to one and a half miles from the sewer outfall were entirely free from the bacillus coli—a fact which indicates that they were beyond the range of sewage contamination and that they might be regarded as perfectly safe for edible purposes. In this fact also we have evidence that shell-fish under normal conditions do not contain this micro-organism and that its presence is therefore an invaluable indication of sewage contamination. It also affords support to those who contend for the proper supervision of oyster, cockle, and mussel beds and laying grounds with a view to their protection against pollution by sewage. It was only in the third series of specimens examined that any trace of a bacillus resembling that of typhoid fever was found and there it was very manifest and abundant. In plate cultures from three cockles collected at 200 yards and one cockle and one "muscin" collected at 600 yards below the sewer outfall it was readily detected. It was a remarkable fact that this bacillus was obtained in great numbers and almost in pure culture in one of these plates. The shell-fish which yielded this almost pure growth was a cockle found on the surface at 200 yards from the sewer outfall. Surface cockles are regarded by cockle-gatherers as "sick" and are carefully avoided by them. It is, however, just such cockles as the inexperienced would be likely to pick up and to partake of, even in the raw condition. As regards the specificity of this bacillus it was found to have all the microscopical and cultural characteristics of the typhoid bacillus. Further, it gave the characteristic typhoid reaction with human typhoid serum and with serum obtained from a guinea-pig immunised against typhoid fever. The finding of this bacillus in such numbers and in so many individual shell-fish is so exceptional that it was repeatedly subjected to trustworthy culture tests and to repeated serum tests and always with the result of proving its identity in every respect with the typhoid bacillus obtained from a case of typhoid fever. The conclusions arrived at are: (1) All the edible shell-fish within the area of sewage contamination showed by the presence of virulent bacillus coli excremental pollution and their consumption must therefore be regarded as highly prejudicial to health; (2) the shell-fish beyond the range of sewage contamination were found to be normal and perfectly safe for edible purposes; and (3) certain shell-fish (cockles and "muscins") within the area of sewage contamination showed the presence of the bacillus of typhoid fever in great number and the consumption of similarly infected shell-fish by holiday visitors in the end of July would sufficiently explain the outbreak of typhoid fever which occurred amongst them after return to their own homes in Glasgow and elsewhere.

University of Glasgow.

The opening of the winter session took place on Oct. 16th. The number of students already enrolled in the various classes is large but another week will require to pass before the work of the session is in full swing. One effect of the Carnegie Trust has been to establish a more uniform rate of fees in the different Scotch universities. Thus, in Glasgow there has been an increase in the fees of most of the medical classes. Formerly for most of them the fee was three guineas, but now it is four guineas, as in Edinburgh.

Nichol Memorial Window.

An interesting ceremony took place on Oct. 17th in the Bute Hall of the University of Glasgow where a memorial window was unveiled. This window, executed by Mr. Henry Holiday of London, was presented to the University by Mr. William Jack, LL.D., professor of mathematics, and his two sons, Dr. William R. Jack and Mr. Adolphus A. Jack, in memory of John Pringle Nichol, LL.D., the celebrated professor of astronomy, his son John Nichol, LL.D., professor of English literature, and his daughter Mrs. Jack. The window was presented to the University by Professor Jack in the names of himself and his sons. Principal Story accepted the gift on behalf of the University. Lord Kelvin and Professor John Ferguson also took part in the proceedings. Professor Jack and his sons received their friends in the Randolph Hall after the conclusion of the ceremony.

Anderson's College Medical School, Glasgow.

The winter session of this school was opened on Oct. 16th by Major Ronald Ross, C.B., F.R.S., professor of tropical medicine, University of Liverpool, who delivered an address on Medical Science and the Empire. He said that if half of the world was not to remain inaccessible to civilisation the diseases which were the scourges of the tropics would have to be overcome. That could not be done by the soldier, by the politician, or by the trader, but only by the efforts of the medical profession. In the evening Major Ross was entertained to dinner in the Council Hall at the City Chambers. On the invitation of the Lord Provost (Sir John Ure Primrose, Bart.), the chairman (ex-Bailie W. F. Anderson) and the members of the health committee a large representative company was present. Major Ross, in replying to the toast of his health, said that the way in which malaria was carried had been definitely ascertained and he would like to see a more general effort by the authorities in this country to deal with the prevention of it in a really business-like manner. Liverpool and Manchester had been actively engaged with this question for a long time and they felt assured that if Glasgow would act with them it would have a good effect. The Lord Provost, in replying to the toast of "The Corporation of the City of Glasgow," proposed by Sir Hector C. Cameron, said that he had no doubt that the corporation would be very willing to support Major Ross in his project of imperial and international coöperation for the prevention of malaria.

St. Mungo's College, Glasgow.

The winter session was opened on Oct. 15th, when an interesting address was delivered to a large gathering by Dr. David N. Knox on the History of Surgery in the Royal Infirmary.

Obituary.

Many will learn with regret of the death at Cradock, Cape Colony, of Mr. Robert Fergus Hutchison, M.B., Ch.B. Aberd., son of Mr. Thomas Hutchison, Ingleside, Cults. Dr. Hutchison had for some time been in weak health and more than a year ago he went to South Africa where he at first showed signs of recovery, only to be seized some weeks ago by a fatal illness. The deceased, who was 28 years of age, graduated in 1898. He subsequently devoted himself to bacteriological work and pursued his studies in London and Paris, returning to Aberdeen a few years later as assistant to Professor D. J. Hamilton. In the line of research which he had chosen Dr. Hutchison gave promise of attaining high distinction.

The Mitchell Family and Marischal College, Aberdeen.

The suggestion that some fitting memorial of the late Mr. C. W. Mitchell of Jesmond Towers, Newcastle-on-Tyne, should be secured for Marischal College, Aberdeen, has been received with general favour. There is already in the picture gallery of Marischal College a bust of Mr. Mitchell's father, the late Dr. Charles Mitchell, and a proposal has informally been made to the effect that a companion bust of Mr. C. W. Mitchell might also be procured for the picture gallery. The total sum which father and son gave to the University of Aberdeen was upwards of £54,000. Dr. Mitchell gave in all £33,000 towards the extension scheme, while Mr. C. W. Mitchell extinguished the debt on the University amounting to £21,171. The cheque for the final instalment of this sum was recently received from Mrs. C. W. Mitchell who is deeply interested in the extension scheme.

Rectorial Address at the University of Aberdeen.

The Right Hon. C. T. Ritchie, M.P., Lord Rector of the University, is to give his rectorial address on Oct. 29th and on the occasion of his visit is to be entertained by the Senatus.

Oct. 20th.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

Royal College of Physicians of Ireland.

THE annual meeting of the Royal College of Physicians of Ireland was held on Oct. 19th when the officers for the ensuing year were elected. A motion expressing regret for the recent death of Sir George F. Duffey was passed in silence. Dr. L. Atthill tendered his resignation of the office of representative of the College on the General Medical Council and Sir John W. Moore was elected thereto.

The Granard Union Trouble.

At the last meeting of the board of guardians which took place at Granard on Oct. 19th a resolution was passed appointing as master the official who was recently dismissed by sealed order of the Local Government Board. A conciliatory letter was read from Dr. J. M. S. Kenny in which he again expressed "regret for the unpleasantness of the past." One of the guardians proposed that it should be thrown into the waste-paper basket. It was afterwards, however, decided to forward it to the bishop, Dr. Hoare. Major Fane, who represented the Local Government Board, said that the Board would appoint a master very soon and he warned the guardians that if it became necessary to replace them by two paid guardians it would cost the ratepayers £500 per annum.

Monkstown Hospital.

At a meeting of the committee of the Monkstown Hospital held on Oct. 15th Sir Charles B. Ball was appointed honorary consulting surgeon to the institution.

Smiley Hospital, Larne.

The Smiley Cottage Hospital, Larne, founded through the munificence of Sir H. H. Smiley, Bart., Larne, and endowed by him to the extent of £5000, is now completed and will be ready in a few weeks for the reception of patients. There are wards for male and female patients, each for six adults, and there are in addition spacious day rooms so designed that in case of emergency four additional beds may be placed in each, which will bring the total accommodation of the ground floor up to 20 beds. There is an admirably fitted-up operating room and the most up-to-date sanitary arrangements have been supplied. The hospital will be under the management of a representative consultative committee and a ladies' working committee. The medical staff will be the medical men resident in Larne and Ballyclare.

Queen's College, Belfast.

The session opened on Oct. 20th in the medical faculty. Dr. Max Freund has been appointed Professor of Modern Languages in place of Dr. A. L. Meissner, and Dr. John McLiesh has been selected to lecture on Vaccination. Great sorrow has been felt at the news of the death on Oct. 18th of Professor J. Purser who for many years was professor of mathematics and who trained three senior wranglers, Allen, Larmor (secretary of the Royal Society), and Orr. Old friends of the late Dr. Charles MacDonall will be pleased to hear that an interesting book by him, "The Origin of the Legend of the Holy Grail," edited by his widow, has just been published.

Royal Victoria Hospital, Belfast.

On Oct. 20th in the extern room of the new Royal Victoria Hospital Dr. J. Walton Browne, senior surgeon, delivered an interesting opening address before a crowded audience of students and practitioners. After welcoming the students at the beginning of a new winter session Dr. Browne gave a full and very much appreciated account of the history of the Belfast School of Medicine from its earliest beginnings up to the present time when clinical work begins in the new and beautiful hospital recently opened by the King.—At a meeting of the corporation of the hospital held on Oct. 19th a motion was passed authorising the board of management to sell or to let all or any portion of the old hospital property belonging to the corporation situated in Frederick-street and Lancaster-street, Belfast. The city corporation had the first offer of the place to use it as a temporary fever hospital until the new city hospital was ready but it declined. The income derived from the old hospital is to go to the support of the Shaftesbury Ward in recognition of the generous treatment which had always been received from the Donegal family.

Death of Dr. William Dobbin.

Dr. William Dobbin of Banbridge, co. Down, died recently in Belfast, in his sixty-first year. For some months past he had had symptoms of intestinal obstruction and on Oct. 16th Professor Thomas Sinclair resected a portion of the colon, but the patient's strength failed and he died on the night of Oct. 17th. Dr. Dobbin was the eldest son of a Presbyterian clergyman, the Rev. W. Dobbin of Annaglone, co. Down. He studied at Queen's College, Belfast, where he had a very distinguished career. In 1867 he graduated as M.D. in the Queen's University and in 1886 he became a Fellow of the Royal College of Surgeons in Ireland. He practised in Banbridge, where he was medical officer of the dispensary district and here he gathered round him a large *clientèle* who greatly esteemed and valued him for his professional knowledge. He leaves a widow, one daughter, and two sons, one of the latter being a member of the North-east Bar and the other an M.D. of Edinburgh University.

Oct. 20th.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

The Cerebro-spinal Fluid of Patients in the Secondary Stage of Syphilis.

AT the meeting of the Hospitals Medical Society which was held on Oct. 9th M. Ravaut communicated in his own name and in that of M. Thibierge some statistics based upon the cytological examination of the cerebro-spinal fluid in 118 patients suffering from the secondary stage of syphilis; 54 of these patients had either no obvious secondary symptoms or only showed roseola and mucous or cutaneous plaques. Seven of these only gave a definite lymphocyte reaction, whereas out of 55 patients who showed pigmentary syphilides, papular syphilides, or syphilitic psoriasis, 41 showed a definite lymphocyte reaction, in some cases very marked. Two patients suffering from syphilitic alopecia and two other patients in which facial paralysis had supervened during the secondary period showed marked lymphocytosis Of five patients suffering from syphilitic iritis one only showed lymphocytosis In all the patients who showed the cellular reaction the quantity of albumin which only exists in very small quantity in normal cerebro spinal fluid, was much increased It would seem, therefore, that these facts prove that in patients affected with secondary syphilis there exist together with certain cutaneous reactions nervous reactions which are to be diagnosed by an examination of the cerebro spinal fluid and these nervous reactions would appear to develop on parallel lines with those of the skin The reactions should be regarded as one of the many manifestations of syphilis and when present would appear to show that the treatment should be very thorough

A Scheme for a Hospital for Infectious Diseases

Among the new buildings included in the great plans which have been taken in hand by the Assistance Publique and which have been approved by the Prefect of the Seine and by the Municipal Council is a hospital for infectious diseases which it is intended to build at Ivry sur Seine, in the district of Vitry, a building which is intended to replace a very poor hospital at present in existence at La Porte de Flandre Here it is intended to treat patients suffering from typhoid fever, from small pox, from diphtheria, and should occasion arise those afflicted with plague or cholera The prospect, however, has no charms for the inhabitants of the neighbouring quarter of Paris—namely, that of the Port-à-l'Anglais in the division of Vitry They have protested for some long time but the Assistance Publique has taken no heed This body promises to isolate the building in an absolutely satisfactory fashion, but the promise has not assured those interested in the matter and they have sent a petition to the Prefect of the Seine begging him to ask the administration of the Assistance Publique to give up the idea of building a hospital for infectious diseases at a distance of only 250 metres from the communal school at Port à l Anglais which educates no less than 900 pupils The Assistance Publique, however, declares that the fears of the inhabitants of Ivry are groundless and the best proof which is brought forward of the harmlessness of the proposed hospital is the fact that it will be situated almost alongside a large almshouse where there are some 2500 aged persons for whom nobody seems to have any fear

French Congresses

The sixteenth Congress of the French Association of Surgery was opened at Paris on Oct 19th in the large theatre of the Paris Faculty of Medicine The seventh congress of the French Association of Urology will be opened at Paris on Oct 22nd in the Faculty of Medicine

A New Method of Suicide

A nurse at one of the hospitals has just tried a new way of committing suicide—namely, by swallowing two tubes of Eberth's pure culture of the typhoid bacillus On the following day and the day after that she felt no inconvenience On the third day she had some headache but no fever On the sixth day she felt heavy and stupid and experienced great weakness in her legs, being obliged to take to her bed On the seventh day her temperature was in the morning 37 6° C and in the evening 38 6° C On the eighth day she had two attacks of epistaxis and her temperature in the evening was 40 2° C Several rose spots were also visible On the tenth day serum reaction was positive Otherwise the typhoid fever followed its normal course but it was a very severe attack and the patient had in all 176 baths The remarkable points of this case are the very short duration of the period of incubation—namely, only two days—and the rapid appearance of the rose spots, eight days after infection The physicians who reported the case—viz , M Duflocq and M Voisin—explained the very short duration of the incubation period by the large quantity of bacilli which were introduced at one time into the digestive tract

BERLIN.

(FROM OUR OWN CORRESPONDENT)

Professor Behring on Tuberculosis

THE most remarkable feature of the recent Congress of German Naturalists and Medical Men was the address on tuberculosis delivered by Professor Behring He commenced by remarking that tuberculosis was an extremely common and widespread disease A series of necropsies made by Professor Naegeli at the Pathological Institute of Zurich showed that in every instance signs of tuberculosis were present in persons over 30 years of age, in 96 per cent of those from 18 to 30 years, in 50 per cent of those from 14 to 18 years, in 33 per cent of those from five to 14 years, and in 17 per cent of those from one to five years Similar results were obtained in living persons by Dr Franz, an Austrian army medical officer, who found that 68 per cent of the men of an Austrian regiment reacted positively to the tuberculin test It had been said that everybody was somewhat tuberculous, and this was true, but tuberculous infection did not always mean pulmonary phthisis To produce phthisis two factors were necessary—namely, (1) a *tuberculous focus and (2) bodily conditions which favoured* the development of tuberculosis Professor Behring was of opinion that communication of pulmonary tuberculosis to adults by contagion had not yet been demonstrated In the cases of butchers laboratory servants, and others who contracted cutaneous tuberculosis it had never been proved that pulmonary tuberculosis had ensued The speaker then alluded to the statistics concerning nurses, prisoners, and other classes of the community which were especially liable to develop phthisis It was, according to him, not their free exposure to infection but the conditions of their life which predisposed them to phthisis, the process being in reality the conversion of a latent focus of disease into an active one Medical men engaged in laryngological practice were exposed to continual risks of infection but nevertheless tuberculosis was not frequent among them because of the absence of other prejudicial influences, such as insufficiency of food The fundamental theory of Professor Behring is that tuberculosis nearly always begins at the earliest period of life and that the germs are communicated to children *by milk. He said that his views might at first sight appear* rather peculiar, for if infants were not suckled by the mother the milk on which they were fed when brought up by hand was boiled or even sterilised Adults, on the contrary, usually drank milk without previously boiling it or taking any other precaution The cause of the liability of infants to become infected was not the contamination of the milk alone but in a great degree the condition of their gastro intestinal canal which by reason of its great permeability was not capable of protecting their systems against the invasion of germs Dr Romer, Professor Behring's assistant, found that in newly born animals albuminates penetrated through the mucosa into the circulation quite unaltered, just as if they had been directly introduced into the blood , in the intestines of adult animals, on the contrary, the albuminates were transformed into soluble peptonates previously to being absorbed Attenuated cultures of anthrax bacilli given with their food to newly born guinea pigs appeared afterwards in the blood Cultures of tubercle bacilli administered in the food always pro*duced tuberculosis of the glands in newly born and very* young animals , with older animals, on the other hand, this occurred only sometimes and not unless very virulent cultures in great quantities had been taken Although the virus was ingested and infection communicated at a very early age, many years might pass before the disease became recognisable by the tuberculin test Under prejudicial influences, *such as exhausting illness, chills, bad* food, unwholesome dwellings and the like the tuberculous infection might then develop into pulmonary phthisis From this point of view Professor Behring spoke favourably of the hygienic and dietetic treatment of pulmonary phthisis His principal object, however, was to discover a method which, like Jenner's vaccination against small pox, would act against tuberculosis and would eventually render sanatoriums and other therapeutic measures unnecessary Speaking of the tuberculosis of cattle he stated that this disease was more prevalent in these animals than was generally believed ; the presence or absence of latent tuberculosis could be ascertained by the tuberculin test with absolute certainty He then alluded to the method devised by him which enabled cattle to be immunised by injections of an antitoxic sub-

preserving these immunising substances so that they might be sent abroad without losing their efficacy Concerning human tuberculosis Professor Behring stated that his researches were not yet finished , he said that for the prophylaxis of tuberculosis in human beings two ways were open—namely, either isopathic immunisation or treatment by antitoxins. He thought that isopathic immunisation might be accomplished in the human species by the inoculation of a relatively attenuated virus of tuberculosis; the antitoxin used for cattle was, however, not fit for that purpose, and even if an immunising substance had been already obtained in that way he would hesitate to inoculate children with it. Among calves treated by the injection of attenuated cultures of bacteria one in 500 might die in consequence of the inoculation and in the human subject it would be obviously impossible for such a responsibility to be accepted deliberately. It was conceivable, however, that the isotherapeutic protective immunisation might become available for children if his experiments succeeded so far as to allow the administration of the attenuated virus of tuberculosis together with food by feeding infants on the milk of immunised cows. As his researches were not yet finished he was unable to supply a remedy against tuberculosis. In conclusion Professor Behring criticised the theories of Professor Koch on the non-identity of human tuberculosis and perlsucht. From the fact that bacilli of human tuberculosis did not produce perlsucht in cattle Professor Koch has concluded that the two species are not identical: this, however, was erroneous. Jennerian vaccine did not produce variola in the human subject, nevertheless no one believed that the virus of vaccine and that of variola were different. Professor Koch, moreover, relied on the fact that infants very seldom contracted intestinal tuberculosis; this argument has, however, now been refuted by his (Professor Behring's) researches on the permeability of the infant's intestinal mucosa. Professor Behring was therefore strongly opposed to any relaxation of the milk control in the manner suggested by Professor Koch. Finally, he said that although some of Professor Koch's views might require to be reconsidered he must ever be regarded as one of the most eminent investigators in connexion with tuberculosis.

Oct. 20th.

SWITZERLAND.

(FROM OUR OWN CORRESPONDENT.)

Swiss Balneological Society.

THE annual meeting of the Swiss Balneological Society took place on Oct. 4th at the picturesque little town of Rheinfelden, celebrated for its saline baths. The salt beds above which Rheinfelden is situated are 114 metres (380 feet) deep and were discovered in 1844. A number of hotels now provide for the accommodation of the thousands of health-seekers who annually frequent the place in search of relief from manifold ailments, such as chlorosis, amenorrhœa, metritis, disease of the uterine adnexa, scrofula, rheumatic and gouty affections, chronic heart disease, and the various neuroses.—Dr. Keller of Rheinfelden, well known in the scientific world by his various treatises on the physiological and clinical effects of saline baths, spoke on the geological conformation of Rheinfelden and its surroundings. The saline water (Soole) was, he said, the strongest in Europe, containing 311·6 parts of chloride of sodium in 1000 parts of fluid, so that the saline constituent formed 31 per cent. (Sea water contains from 3 to 4 per cent. of chloride of sodium.) The strongest saline baths on the continent, well known as spas, were Inowrazlaw, in Germany (30 per cent.); Bex, in Switzerland (27·5 per cent.); Hall, in the Tyrol (25 5 per cent.); Ischl, in Austria (23·6 per cent.); Salies de Béarn, in France (21·6 per cent.); and Kreuznach, in the Rhine province (16·4 per cent.).—Dr. Theodore Zangger of Zürich spoke on the various indications for the use of weak and strong saline baths. He distinguished normal baths (up to 3 per cent. strength corresponding to sea water), stronger baths (up to 6 per cent.), and very concentrated ones of 8, 10, 12, 25, and even 31 per cent. As the Rheinfelden and Bex saline waters were used for bathing purposes all over Switzerland and were prescribed most extensively both for home use and in bathing establishments it was very desirable that they should be of the proper strength and carefully supervised. Individual treatment was indispensable. Of late the higher strengths were much in vogue but they had to be prescribed with care. The effects of 3 and 6 per cent. saline baths differed greatly, as, in fact, Dr. Keller had demonstrated many years ago by physiological experiments. The former increased diuresis by from 10 to 23 per cent. and the excretion of chlorides by from 31 to 42 per cent.; the latter reduced diuresis by 2·7 per cent. and caused only a small increase of the excreted chlorides (6 per cent). Such variations should receive clinical investigation. Strong saline solutions unquestionably had not only their indications but also their contra-indications and the latter deserved to be carefully studied. They were best prescribed at spas, where the patient had from four to six weeks' complete rest for a proper course of treatment.—Dr. Keller, in his reply, said that it was impossible to give distinct outlines of the indications with regard to strong saline baths. Some patients, especially those with long-standing bone affections, with metritis and myomatous tumours, derived the greatest benefit from them, such as could not be obtained from weak saline baths. Thus other saline spas on the continent (Reichenhall, Ischl, and Inowrazlaw) were introducing stronger baths and following the example which the French spas, especially Salies de Béarn in the Pyrenees, had given for many years.—After the meeting the members inspected the various buildings in connexion with the saline baths of Rheinfelden and assembled at the Grand Hotel for the annual dinner. In 1904 the annual meeting will take place in September at Lugano and Dr. Reali of Lugano has been elected president.

Zürich, Oct. 19th.

CANADA.

(FROM OUR OWN CORRESPONDENT.)

Canadian Medical Association.

THE thirty-sixth annual meeting of the Canadian Medical Association was held at London, Ontario, on August 25th, 26th, 27th, and 28th, under the presidency of Dr. Walter H. Moorhouse of that city, who is dean of the medical department of the Western University. It proved to be the second largest meeting in the history of the organisation, being only eclipsed by that of last year which was held at Montreal. Dr. James Newell (Watford, Ontario) read a paper on the Surgical Treatment of Hallux Valgus and Bunions. Dr. R. Ferguson (London, Ontario) presented an interesting specimen of an Incompletely Developed Uterus and Appendages removed from the sac of an inguinal hernia. The patient was 32 years of age and was married but had never menstruated. The external genitals and mammary glands were normally developed but the vagina was a mere cul-de-sac without trace of cervix or os. Every four or six weeks the patient had been subject to violent headaches which drove her to the point of distraction. Four and a half months had elapsed since the operation and she had been absolutely free from the attacks of headache. This finished the forenoon session of the first day. In the afternoon the meeting assembled in surgical and medical sections. In the former section Dr. A. B. Atherton (Fredericton, New Brunswick) was appointed chairman and in the latter Dr. R. W. Bruce-Smith (Brockville, Ontario). In the medical section the first question taken up and discussed was the Treatment of Typhoid Fever, which was opened by Dr. W. P. Caven (Toronto). In the opinion of Dr. Caven the conditions calling for active treatment are tympanites and hæmorrhage. For the former he recommended turpentine and asafœtida and for the latter morphine. There should be routine sponging in every case, tepid where the temperature was below 102° F. but above that degree cold sponging should be carried out. Dr. John Herald (Kingston, Ontario) continued the discussion, stating that he would not employ internal medication in ordinary cases. In hæmorrhage he considered the ice-bag to be as useful as morphine. Dr. H. A. McCallum (London, Ontario) lauded strychnine throughout the attack as the most important agent in the treatment of this disease. Dr. J. T. Duncan (Toronto) next read a paper on the Size of the Pupils as an Aid to Diagnosis. Dr. Hornibrook (Cherokee, Iowa, U.S.A.) read a paper discussing the most recent phases of Auto-intoxication. The paper which excited the keenest interest in this section was that by Dr. Jennie Drennan (St. Thomas, Ontario) on the Physiological Generative Cycle in Woman. She stated that evolution was incident to all forms of life. The factors in every phase of life were adaptation to environment and heredity. Structure was determined by function and function was the product of environment. The function of the female mammal was ovulation, pregnancy, and gestation. This cycle had become interrupted by ovulation and menstruation as the result of adaptation to a pernicious environment. The remedy to effect the restoration of the natural cycle would in time be improved environment. In the surgical section Dr. Hadley Williams (London, Ontario) reported on, and exhibited, a very interesting case of Gunshot Injury of the Shaft of the Humerus with destruction of two inches of the musculo-spiral nerve. Four months after the accident the case was brought to him at which time non-union and complete paralysis were present. The nerve and two inches of bone were dissected out and the nerve ends were brought together by through-and-through silk sutures. There was neither union of bone nor relief of the paralysis as a result of this operation. Four months after the first operation he performed a second in which the ends of the bone were maintained in apposition by means of a silver plate secured to the shaft as a splint by four silver screws. In six weeks the bone had united and in nine months from the suture of the nerve ends the paralysis had disappeared and recovery was complete. The treatment of the case was original and the essential details were pointed out as being firm apposition of the fragments by means of the plate and screws and the avoidance of tension on the nerve ends. By placing muscle between the bone and nerve involvement in the callus was avoided. Dr. Henry Howitt (Guelph, Ontario) then reported two cases of Hour-glass Contraction of the Stomach; one was complicated by an ulcer on the posterior wall of the stomach and the other by cancer. Both cases were much relieved by operation. Dr. R. P. Robinson (Ottawa) reported two cases of operation for Morbus Coxæ resulting in cure without shortening, although both cases had reached the abscess stage. Dr. Robinson does not allow his patients to walk for six months. Dr. J. A. Hutchison (Montreal) reported five cases operated on for Typhoid Perforation. The fifth only was successful. The rate of recoveries with operation was now 20 per cent.

A general session was held on the evening of the first day at which Dr. Moorhouse delivered the annual presidential address. He touched upon the importance and advantage of attending meetings like those of the Canadian Medical Association which year by year was becoming of great influence in the medical life of the Dominion of Canada. Charlatanism should be resisted with a steady and constant hand. Dominion registration was something to be desired and he hoped that Quebec would come to its senses and not further frustrate the labours of Dr. Roddick. Following the able deliverance of the President, Dr G. M. Gould (Philadelphia—the editor of *American Medicine*) read an important paper on the Rôle of Eye-strain in Civilisation and Medicine. A lantern lecture on the Open-air Treatment of Consumption was then conducted by Dr. J. H. Elliott, medical superintendent of the Gravenhurst Sanatorium. Following this Dr. E. J. Barrick (Toronto) read a paper advocating the establishment of municipal sanatoriums, the outcome of which was a resolution urging the Government to enact legislation providing for municipal sanatoriums for consumptives.

On the forenoon of the second day, before assembling at the convention hall, clinics were held and operations were performed at the two general hospitals of London. Much regret was expressed at the absence of Dr. Matthew D. Mann (Buffalo, U.S.A.) who was to deliver the address in Gynæcology at the commencement of the morning session. In the medical section Dr. Sprague (Stirling, Ontario) gave a character sketch of the Country Doctor in Canada, and being somewhat of a cartoonist he was able to make the paper a very interesting one. Dr. George F. Butler (medical superintendent of the Alma Springs Sanatorium, Alma, Michigan, U.S.A.) read a very important and able paper on the Inter-Relations of Diabetes and other Constitutional Diseases, a paper which was highly commended by Sir J ve (Toronto), and Dr. he surgical section Dr. T .) read a paper entitled al Anastomosis." In his procedure he draws the gangrenous coil out of the abdomen far enough to permit him to unite the two limbs of the bowel at a point where they seem healthy by means of a rubber ligature. All of that part which is liable to slough is then fastened outside the abdomen and the wound is closed around it. The immediate result is a false anus and in two or three days a new channel has been cut by the rubber ligature and the false anus becomes unnecessary. It may then in time close spontaneously or be closed by the simple operation of inverting and suturing the ends. The advantages over other methods are thus described by Dr. McGraw: simplicity and quickness of application; its aseptic quality, for the rubber fills the opening through which it passes so completely that no extravasation is possible; the delay in opening the passage until the intestines have become well glued together; and the ability to make with it a communication of any desired length. An interesting case of Thrombosis of the Femoral Vein following Laparotomy was then reported by Dr. E. R. Secord (Brantford, Ontario). The thrombosis occurred two weeks after an aseptic operation for double inguinal hernia in which the wounds healed by first intention. The thrombosis was on the left side, where a truss had been worn for 12 years. The address in Surgery was delivered by Dr. Alexander Hugh Ferguson (Chicago) and the address in Medicine by Dr. McCallum. The former took for his subject the Surgery of To-day and the latter read a very able address on the Influence of the Lymph Circulation. In the medical section on the afternoon of the second day Dr. E. G. Wood (Nashville, Tennessee), professor of medicine in the University of Tennessee, read a carefully prepared paper on the Cardiac Affections in Influenza. This excited a good deal of discussion. Other papers contributed were one by Dr. Alexander McPhedran (Toronto) on Amyotrophic Lateral Sclerosis and one by Dr. A. L. Benedict (Buffalo, New York). Dr. Adam Wright (Toronto) read a practical paper on Concealed Accidental Hæmorrhage. Various excursions and a banquet concluded the day's work.

At the business meeting of the morning session of the fourth day the following officers were elected: President, Dr. S. J. Tunstall (Vancouver, British Columbia); treasurer, Dr. H. B. Small (Ottawa); and general secretary, Dr. George Elliott (Toronto). Vancouver was selected as the place of meeting in 1905. A committee was appointed to invite the British Medical Association to meet in Toronto in 1905.

Oct. 10th.

Medical News.

UNIVERSITY OF CAMBRIDGE.—The following medical degrees were conferred on Oct. 15th:—

Bachelor of Medicine.—J. G. Cooper, Trinity.
Bachelor of Medicine and Bachelor of Surgery.—W. F. L. Day and A. O. M. Fehrsen, Gonville and Caius; and F. P. Edwards, Downing.

The First, Second, and Third (Part I.) M.B. examinations will begin this year on Dec. 14th; the Third (Part II.) M.B. and the M.C. examinations will begin on Dec. 8th.—Professor Howard Marsh has begun his lectures on the Principles of Surgery in the new medical school, the buildings of which are nearing completion.

UNIVERSITY OF EDINBURGH.—At the special graduation ceremonial held in the M'Ewan Hall on Oct. 17th the following degrees and certificate were conferred:—

Doctor of Medicine.—*Edmund Thurlow Potts, England, M.B., Ch.B., 1901.
Bachelor of Medicine and Master in Surgery.—Frederic Russell
or of Surgery.—Roland Thomas
George Augustus Davie
Zealand, †Auckland Ca
Godfrey, India; William Denby Sainter Harrison, England; John Ockert Heyns, Cape Colony
Muhammad Inayat Ali K
Twigge, England; John A
David Charles Welsh, Scotland.
Bachelor of Science.—James Andrew Gunn, M.A.; and in the department of agriculture, Thomas Foster Main and George Clay Muirhead.
Special University Certificate in Diseases of Tropical Climates.—Roland Thomas Graves Aickin, M.B., Ch.B.; Farhat Ali, B.A.,

M B., Ch B.; John Allan, M.B., Ch.B.; Marcus Armly Ash-Kenny, M B., Ch.B.; Muhammad Inayat Ali Khan, M.B., Ch.B.; Charles Edward Marshall, M.B., Ch.B.; and Thomas Theodore Thomson, M.B., Ch.B.

* Commended for thesis.

† Passed the examinations with second-class honours.

FOREIGN UNIVERSITY INTELLIGENCE.—*Bologna:* Dr. Giovanni Vitali of Modena has been recognised as *privat-docent* of Internal Medicine.—*Copenhagen:* Dr. Alexander Vincent has been recognised as *privat-docent* of Physiology and Dr. Axel Blad as *privat docent* of Internal Medicine.—*Freiburg;* Dr. Richard Link has been recognised as *privat-docent* of Internal Medicine, Dr. Karl von Eicken as *privat-docent* of Laryngology, and Dr. W. Herrenknecht as *privat-docent* of Odontology.—*Halle:* the title of Professor has been granted to Dr. A. Tschermak, *privat-docent* of Physiology, and to Dr. Ernst Vahlen, *privat-docent* of Pharmacology.—*Kazan:* Dr. V. Bormann has been recognised as *privat-docent* of External Pathology.—*Königsberg:* Dr. R. Beneke of Göttingen has been appointed to the chair of Pathological Anatomy vacant by the resignation of Dr. Neumann.—*Moscow:* Dr. Talientseff has been appointed Extraordinary Professor of General Pathology.—*Naples:* Dr. Antonio Anile and Dr. Vastarini-Cresci have been recognised as *privat-docenten* of Anatomy, Dr. F. Scotti as *privat-docent* of Internal Pathology, Dr. F. Jacobelli and Dr. L. Rizzo as *privat docenten* of External Pathology, Dr. A. Plantieri as *privat-docent* of Operative Medicine, Dr. L. Mosca as *privat-docent* of Dermatology, and Dr. D. Durante as *privat-docent* of Pædiatry.—*Pavia:* Dr. Tansini of Palermo has been appointed Professor of Clinical Surgery in succession to the late Dr. Bottini.—*Prague* (*German University*): Dr. Fischl, *privat docent* of Anatomy, has been promoted to an Extraordinary Professorship; Dr. Walko has been recognised as *privat-docent* of Internal Medicine.—*Rome:* Dr. Mattoli has been recognised as *privat docent* of Surgical Anatomy and of Operative Medicine.—*Vienna:* Dr. Rudolf Schmidt has been recognised as *privat docent* of Internal Medicine, Dr. Heinrich von Halben as *privat-docent* of Neurology and Psychiatry, Dr. Alexander as *privat docent* of Otology, and Dr. Pupovac as *privat-docent* of Surgery.

NEW CREMATORIUM FOR THE CITY OF LONDON.—Mr. R. W. Edwards, chairman of the sanitary committee of the Corporation of London, laid the foundation-stone of the new crematorium at Ilford Cemetery, acting for the City of London Burial Board. The ceremony took place on Oct. 14th. The new crematorium is being built in a secluded part of the cemetery. The design is Gothic in style and is intended to harmonise with the existing chapels in its vicinity. The plans provide for a hall 27 feet in length by 24 feet in width for the mourners to assemble in, with a waiting room 13 feet by 13 feet adjacent and leading out of the hall. The catafalque upon which the coffins will rest will be placed in the centre of the hall and an ante-chamber is provided for the attendants between the hall and cremating chamber. The cremating chamber is at the rear of the hall and will be of sufficient size to admit of two cremating furnaces being erected with an arrangement for the bodies being placed in either furnace by means of a traverse. At the present time it is intended to erect only one furnace, the flue for which will be carried up in the centre of an ornamental tower about 80 feet in height. A small auxiliary furnace will be placed at the base of the tower for the more perfect combustion of the gases arising from the cremating furnace and a staircase is provided for access to the summit. There is to be a basement under the cremating chamber from which the furnace will be attended to, also stores for fuel, the entrance to the same being at the rear of the structure. The cost of the work, including the furnace, will be about £7000. Mr. Edwards in the course of his remarks said that the Corporation of London was now leading the way in the special direction of sanitary science, the crematorium being the first in course of erection within any cemetery of the United Kingdom and the first in course of construction by any corporation or municipal body within the vast metropolis of London. When Sir Henry Thompson in the year 1874 introduced in this country the question of the disposal of our revered dead by means of cremation, perhaps it would not be too much to say that the idea was regarded with antipathy and met with a shudder. The late Commissioners of Sewers of the City of London had the question of providing a crematorium brought before them by one of their members in the year 1891 and although meeting with some opposition it was referred to a committee to consider and to report. The committee reported that the commissioners had no power in the suggested direction. Later in the year 1894 the question was again raised on a motion to promote a Bill in Parliament to obtain the necessary powers. This although agreed to at the time was afterwards rescinded. The subject, however, was not lost sight of and on the promotion of a Various Powers Bill in the year 1900 a clause was inserted giving the corporation the necessary powers to erect a crematorium on this spot. The sanitary committee was not slow in moving the exercise of the power obtained and by an order of the Court of Common Council of Jan. 17th, 1901, it was referred to the committee to consider and to report as to the erection of a crematorium in this cemetery under the powers conferred by the Act of 1900, with instructions to submit plans and estimates for the proposed buildings. Later authority was given to the committee to inspect various crematoriums and a subcommittee visited the crematoriums at Hull, Manchester, and Liverpool, and also the crematorium of the Cremation Society of England at Woking. Plans were prepared and ultimately the Court of Common Council sanctioned those now in process of execution.

THE GUILD OF ST. LUKE.—The annual festival service of the Guild of St. Luke was held at St. Paul's Cathedral on Wednesday evening, Oct. 21st. A very large number of the medical profession attended in their robes and were seated under the dome. The musical portion of the service was beautifully rendered by the special choir of the London Church Choir Association under the able conductorship of Dr. Walford Davies. The Magnificat and Nunc Dimittis were Walmisley in "D" minor and the anthem was Brahm's "How lovely is Thy dwelling-place." The service was intoned by Minor Canon Morgan Brown and the lessons, which were taken from the 38th chapter of Ecclesiasticus and the 10th chapter of the Gospel according to St. Luke, were read by the Rev. W. H. H. Jervois, vicar of St. Mary Magdalene, Munster-square, N.W. An eloquent sermon was preached by the Rev. Prebendary Montague Villiers from Job xxxii., verse 8, the preacher addressing himself principally to the problems which continually confront the members of the clerical and medical professions alike and which would be insoluble were it not for the incarnation of Jesus Christ.

ST. GEORGE'S HOSPITAL.—The Rev. Dr. Warre, headmaster of Eton College, distributed the prizes to the successful students of the St. George's Hospital Medical School on Oct. 15th in the board-room of the hospital. Afterwards he gave an address to those present, in which he referred to the system of examinations. He said he was discontented with things as they were and was liable to make others discontented. Yet he saw no remedy, nor was he able to propose anything which would mitigate the evils of the present system and would at the same time satisfy the public conscience as a method of testing competency or judging merit. Before long, however, the question must demand serious consideration upon a wide platform. He would therefore turn their attention at the present time to the subject of sympathy and its value as a personal influence in the noble profession to which their lives and their energies would be devoted. The mere feeling of emotion at the sight of suffering did not give sympathy any right to rank as a virtue. Such feelings had to be schooled and disciplined if the public were to be supplied with physicians and surgeons capable of fulfilling the duties of their calling. It was no part of sound training to repress these feelings altogether or to sear and to harden the heart so that it became incapable of feeling them. True sympathy was not limited to passive impressions which diminished as active habits increased, nor was it purely emotional, but it was something wider and higher and far more richly endowed with power for good than those passive impressions which were the characteristics of its embryonic stage. In the great treasury of professional success there were many chambers, each of which had its own lock and its own key. Knowledge and skill, patience and accuracy, each of these opened a door and each brought its own reward to successful labour. But the innermost chamber of all could only be unlocked and entered by those who through self-discipline had gained the golden master-key of true sympathy. As to the acquisition of this gift and grace of true sympathy he thought it was not possible of attainment by those whose training left them callous to another's pain and whose aspirations were merely selfish. It might be that hospital practice was not altogether favourable to the acquisition of a sympathetic habit of mind, but that was only all the more reason for students to stir up that gift within them in moments of reflection. In private practice a medical man saw all sorts and conditions of men and he would find the need of that sympathy which self-discipline alone could impart. The key to the knowledge of man was true sympathy and to be able to enter into the feelings of another was the first step towards being able to interpret them and in the right interpretation very often lay the secret of relief. He therefore claimed a place for real sympathy in their equipment as medical men.

LITERARY INTELLIGENCE.—Dr. Gerald Leighton (editor of the *Field Naturalist's Quarterly*) has finished his book on "British Lizards" which will be published immediately by Mr. G. Morton, Edinburgh. The work is a companion volume to the author's "British Serpents" which was published two years ago. It is to be copiously illustrated by reproductions of photographs of living lizards taken by Mr. Douglas English.—The August number of the *Maryland Medical Journal* states that Mr. and Mrs. Harold McCormick have endowed a new medical journal to be known as the *Journal of Infectious Diseases.* Its editors will be Professor Ludvig Hektoen and Professor E. O. Jordan of the University of Chicago. The value of the endowment is $125,000.

PRESENTATIONS TO MEDICAL PRACTITIONERS.—Mr. James Rowlands Essex, M.R.C.S. Eng., J.P., of Pontypool, Monmouthshire, was on Oct. 10th presented with an illuminated address by the workmen of the Glyn collieries as a mark of respect and esteem on the occasion of his retirement from practice.—The members of the Druids Friendly Society at Wiveliscombe, Somerset, have presented to Mr. J. Wyatt Pratt, M.R.C.S. Eng., L R C P. Edin., L.S A., who has been lodge surgeon for the past 26 years and is now retiring from practice owing to ill-health, an ormolu-gilt clock and vases and an illuminated address as a mark of their respect and esteem. Miss Pratt was presented with a pair of silver flower vases.

DEATH OF MR. LEWIS A. TALLERMAN.—The death is announced as having taken place suddenly on Saturday last, whilst entertaining some friends at dinner at the Langham Hotel, London, of Mr. Tallerman whose name is well known in connexion with the localised application of superheated dry air. Whether or not Mr. Tallerman was, as he claimed to be, the inventor of the system, which was introduced to the profession in a clinical lecture delivered at St Bartholomew's Hospital on May 23rd, 1894, by Mr. A. Willett, F.R C S. Eng., and thereafter used in that and many other hospitals, he without doubt spent a large sum of money in making known the treatment which bears his name and he was very severe on any similar treatment which he conceived to be an imitation or adaptation of his own. Mr. Tallerman, who amassed a considerable fortune in Australia in commercial pursuits, although of an excitable disposition at times, had withal a genial nature and opened several institutes in different parts of the country for [illegible] the necessitous poor by his [illegible] of 58 years and was buried on [illegible]

THE METROPOLITAN ASYLUMS BOARD AND ALLEGED PREMATURE DISCHARGE OF A SCARLET FEVER PATIENT.—At a meeting of the Metropolitan Asylums Board on Oct. 17th the hospitals committee reported that it had had before it a letter of complaint from the father of a patient at the Grove Hospital named Arthur Wright alleging premature discharge and consequent spread of scarlet fever among other members of his family and claiming compensation. After considering the medical investigator's report upon the case an approved reply was sent to Mr. Wright stating that a close examination into all [illegible] ence of that class or the medical investigator to account for the illness which followed his discharge and pointing out that the rule of the Board was for no patient to be discharged until the medical superintendent of the hospital was of opinion that the patient might leave the hospital without risk of conveying infection or contagion and it was not until that opinion had been formed that his son was discharged. A writ had, however, been served on the Board's solicitors at the suit of the father of the patient claiming damages for negligence. The committee recommended that the Board's solicitors be instructed to take all necessary steps for defending the action. The recommendation was agreed to and the action of the committee was approved.

Dr. Dawson F. D. Turner has been awarded a Keith prize by the Royal Scottish Society of Arts for papers upon improved Roentgen apparatus and other electrical matters.

THE LORD MAYOR AND THE PRESS.—On Saturday evening, Oct. 17th, the Lord Mayor and the Lady Mayoress gave a banquet at the Mansion House "to meet the President of the Institute of Journalists and representatives of the London Press." A large company was present and some interesting speeches were delivered by the Lord Mayor, Mr. Anthony Hope Hawkins, Mr. A. W. Pinero, Mr. Augustin Birrell, K.C., and others.

DONATIONS AND BEQUESTS.—Mrs. Alicia Isabella Hamilton O'Hara of Kingstown, Dublin, has under her will bequeathed £300 to the Eye and Ear Hospital at Dublin.—By the will of Mr Henry Worton Elliott of Birmingham £100 are left to the General Hospital, the General Dispensary, the Queen's Hospital, and the Hospital for Sick Children, Birmingham, respectively.—An anonymous donor has contributed £1000 towards the funds of University College, Bristol.

THE UNIVERSITY OF LONDON.—The first meeting of the Faculty of Medicine in the session 1903-04 will be held at the University, South Kensington, S.W., at 5 o'clock P.M. on Friday, Oct. 30th. The chief items of business are (1) the consideration of communications from various interested bodies with reference to a proposal to establish a degree in veterinary science and (2) the consideration of recommendations to be made to the Senate with reference to the constitution for 1904 of the boards of studies with which the Faculty is concerned.

MEDICO-LEGAL SOCIETY.—A meeting of this society was held on Oct. 13th. The following were elected as officers for the ensuing year. President: Sir William J. Collins. Vice Presidents: Mr. C. H. Hopwood, Mr. A. J. Pepper, Dr. A. Bostock Hill, and Dr. M Hay. Council: Dr. Garson, Dr. C. O. Hawthorne, Dr. T. N. Kelynack, Dr. Harvey Littlejohn, Dr. George Danford Thomas, Dr. F. J. Smith, Dr. W. McCallin, Dr. F. J. Wethered, and Dr. W. Wynn Westcott. Treasurer: Mr. John Troutbeck. Secretary: Mr. R. Henslowe-Wellington, assisted by Mr. S. B. Atkinson.

SOCIETY OF ANÆSTHETISTS.—The annual dinner *of this society was held at the Café Munico on Oct. 16th.*—Mr. C. Carter Braine, the President, received 52 members and guests, among the latter being several ladies, Dr. Urban Pritchard, Mr. Arthur E. J. Barker, Dr. C. J. Cullingworth, and others.—Dr. Cullingworth proposed the toast of "The Society." He said that Sir James Simpson, a gynæcologist, fought a hard fight for anæsthesia and won. Anæsthesia flourished for some time without science but was now on a scientific basis and advancing. He suggested that anæsthetists might sometimes be invited to give a lecture on their own experiences of, and views as to, operators. The former could institute useful comparisons between operators who, by the way, rarely saw each other operate. By publishing transactions the society invited criticism and its proceedings became permanent.—The President, in replying to the toast, avowed that the greatest honour to an anæsthetist was to be President of the society. It had existed now for ten years and started as a semi-social gathering for the discussion of cases. Then there was an influx of country and foreign members and later of practitioners interested in anæsthesia. The membership now was 91. During the present session there would be several clinical meetings. The presence of the lady members and their friends greatly helped to make the dinner a success.—Dr. Dudley W. Buxton proposed the toast of "The Visitors" in a witty speech.—Mr. Barker, in answer, acknowledged the debt of gratitude which surgeons owed to anæsthetists and emphasised the confidence which was placed in them.—Dr. Woollett proposed "The Health of the President" who suitably replied.—During the evening songs and recitations were excellently rendered by Miss Jessie Parker, Mr. Frederick Keel, and Mr. Patrick Kirwan.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward to THE LANCET *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, such information for gratuitous publication.*

ABRAHAMS, BERTRAM LOUIS, M.B., has been appointed Lecturer in Physiology to the Westminster Hospital Medical School.

ARNOLD, FRANK ARTHUR, M.B. Lond., D.P.H. Lond., District Medical Officer of Health, Eastern Transvaal, has been appointed Assistant Medical Officer of Health, Transvaal, Pretoria.

BLETCHLEY, G. P., M.B. Lond., has been appointed Certifying Surgeon under the Factory Act for the Nailsworth District of the county of Gloucester.

BOURKE, JAMES JOSEPH FITZGERALD, L.R.C.P. & S. Irel., has been appointed Medical Officer at Hughenden, Queensland, Australia.

BRIDGER, S., M.R.C.S., L.R.C.P. Lond., has been appointed Certifying Surgeon under the Factory Act for the Southend District of the county of Essex.

BROWN, R. C., M.B., Ch.B. Melb., F.R.C.S. Eng., has been appointed Honorary Anæsthetist to the Alfred Hospital, Melbourne, Victoria, Australia.

CRAIG, J., M.B., M.S. Edin., has been appointed Certifying Surgeon under the Factory Act for the Biddulph District of the county of Stafford.

DANIELL, G. W. BAMPFYLDE, M.R.C.S., L.R.C.P. Lond., has been appointed Instructor in Anæsthetics to the Royal Infirmary, Edinburgh.

DIXON, B. GODFREY, L.R.C.P. Lond, M.R C.S. Eng., L.S.A., has been appointed Medical Officer to the Walton Workhouse, Liverpool.

EDEN, T. WATTS, M.D. Edin., has been appointed Physician to the In-patients at the Chelsea Hospital for Women.

FORSTER, LUCINDA, M.B., B.S. Lond., has been appointed Medical Officer to the Quarantine Office, Suez.

HANSON, F. C, L.M. K.Q C.P.I. and R.C.S.I., has been appointed Certifying Surgeon under the Factory Act for the Bray District of the county of Wicklow.

HARBISON, W. H., L.R.C.P., L.R.C.S. Edin., L.F.P.S G., has been appointed Medical Officer of Health for Wallaroo, South Australia.

HEBB, R. G., M.D. Cantab., has been appointed Lecturer in Pathology to the Westminster Hospital Medical School.

HEWLETT, J. E., M.B., M S. Edin., has been appointed Clinical Assistant to the Chelsea Hospital for Women.

HOPE, EDWARD CULBERTSON, M.R.C.S., has been appointed Medical Officer at Winton, Queensland, Australia.

JOHNSTON, G. JAMESON, M.A., M.B., R.U.I., F.R.C.S.I., has been appointed Honorary Surgeon, Masonic Orphan Boys' School, Dublin.

KANE, ROBERT ENGLISH, L.R.C.P. and S. Edin., has been appointed Medical Officer at Taroom, Queensland, Australia.

LLOYD, W. GIBBS, M Sc., M.B., Ch.B. Vict., has been appointed Assistant Medical Officer to the Walton Workhouse, Liverpool.

LONG, S. H., M.D. Cantab., has been appointed Medical Officer of Health of Cromer.

MACKEY, CHARLES, M.B., Ch.B. Vict., has been appointed Junior Resident Medical Officer, Manchester Children's Hospital, Pendlebury.

MULLEN, W. L., M.D. Melb., has been appointed Deputy Medical Superintendent of the Kew Lunatic Asylum, Victoria, Australia.

O'MAHONY, JOHN J., M.B., B.S. R.U.I., has been appointed Medical Officer of the Goleen District of Schull, Bantry.

PENNY, W. R., M.R.C.S., L.R.C.P. Lond., has been appointed Certifying Surgeon under the Factory Act for the Greenodd District of the county of Lancaster.

RIVIERE, CLIVE, M.D. Lond., M.R.C.P. Lond., has been appointed a Physician to the Out-patients at the City of London Hospital for Diseases of the Chest.

ROBERTSON, MCGREGOR J., M.B., Ch.B. Edin., L.M., has been appointed Assistant Master of the Coombe Lying-in Hospital, Dublin [corrected notice].

ROE, WM. FRANCIS, L.R.C.P. Irel., L.R.C.S. Irel., L.M., has been appointed Physician to the Holloway and North Islington Dispensary.

STARK, A. CAMPBELL, B.Sc., has been appointed Lecturer in Biology to Westminster Hospital Medical School.

STEWART, C. P., M.B., M.S. Edin., has been appointed Certifying Surgeon under the Factory Act for the Perth District of the county of Perth.

WILSON, J. CLARK, M.D. Edin., has been appointed Clinical Assistant to the Samaritan Free Hospital.

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement (see Index).

BELGRAVE HOSPITAL FOR CHILDREN, Clapham-road, Kennington, S W.—Resident Medical Officer for six months. Salary at rate of £40 per annum, with board and lodging.

BIRKENHEAD UNION INFIRMARY, WORKHOUSE, AND SANATORIUM.—Resident Assistant Medical Officer. Salary £120 per annum, with board, washing, and apartments.

CANCER HOSPITAL, Fulham-road.—Supervisor of Electrical Arrangements. Honorarium £26 5s. annually.

CHELSEA HOSPITAL FOR WOMEN, Fulham-road, S.W.—Physician.

DARLINGTON HOSPITAL AND DISPENSARY.—House Surgeon, unmarried. Salary £120, with board and lodging.

GLASGOW UNIVERSITY.—Three Examiners, each in Anatomy, Medical Jurisprudence, and Midwifery. Salaries, Anatomy £80, Medical Jurisprudence £50, and Midwifery £50, with hotel and travelling expenses. Also Examiner in Botany. Salary £50, with hotel and travelling expenses.

GORDON HOSPITAL FOR FISTULA, &c., Vauxhall Bridge-road, S.W.—House Surgeon. Honorarium £40 for 12 months, with board and residence.

GRAVESEND HOSPITAL.—House Surgeon. Salary £100 per annum, with board and residence.

HACKNEY UNION WORKHOUSE AND INFIRMARY, Homerton.—Second Assistant Medical Officer, unmarried. Salary £120 per annum, with rations, apartments, washing, and attendance.

HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST, Brompton.—Resident House Physician, for six months. Honorarium of £25.

HOSPITAL FOR SICK CHILDREN, Great Ormond-street, W.C.—House Surgeon, unmarried, for six months. Salary £20, with board and residence. Also Honorary Radiographer.

HOSPITAL FOR WOMEN, Soho-square, London, W.—House Physician for six months. Salary £30.

INDIAN MEDICAL SERVICE, India Office.—Twenty Commissions.

LEEDS GENERAL INFIRMARY.—Resident Casualty Officer. Salary £100 a year, with board, lodging, and washing.

LONDON HOSPITAL, Whitechapel, E.—Physician to the Skin Department.

MANCHESTER NORTHERN HOSPITAL FOR WOMEN AND CHILDREN, Park-place, Cheetham-hill-road.—Honorary Surgeon for Children.

MELBOURNE, UNIVERSITY OF.—Chair of Physiology and Histology.

NEWCASTLE-UPON-TYNE UNION.—Assistant Medical Officer. Salary at rate of £150 per annum, with apartments, rations, and washing.

NORTH-EASTERN HOSPITAL FOR CHILDREN, Hackney-road, N.E.—House Physician for six months. Salary at rate of £80 per annum, with board, residence, and laundry. Also Assistant Physician. Also Resident Medical Officer. Salary £120 per annum, with board, residence, and washing.

NOTTINGHAM CHILDREN'S HOSPITAL.—House Surgeon, unmarried, for six months. Salary at rate of £100 per annum, with board and residence.

PORTSMOUTH ROYAL HOSPITAL.—Assistant Surgeon for six months. Salary at rate of £50 per annum, with board, residence, &c.

QUEEN CHARLOTTE'S LYING-IN HOSPITAL, Marylebone-road, N.W.—Assistant Resident Medical Officer for four months. Salary at rate of £50 per annum, with board, residence, and washing.

ROCHDALE INFIRMARY.—Resident Medical Officer, unmarried. Salary £100 per annum, with board, residence, and washing.

ROYAL HOSPITAL FOR DISEASES OF THE CHEST, City-road, E.C.—Assistant Physician.

ROYAL LONDON OPHTHALMIC HOSPITAL, City-road, E.C.—Senior House Surgeon. Salary £100, with board and residence.

ST. THOMAS'S HOSPITAL.—Resident Assistant Physician.

SALISBURY INFIRMARY.—Assistant House Surgeon. Salary £75 per annum, with apartments, board, and washing.

SOUTH UIST PARISH (NORTHERN DIVISION).—Medical Officer. Salary £70.

SUNDERLAND, COUNTY BOROUGH AND PORT OF.—Medical Officer of Health. Salary £520 per annum.

SUSSEX COUNTY HOSPITAL, Brighton.—House Surgeon, unmarried. Salary £140 per annum, with board and residence.

WESTERN DISPENSARY, Rochester-row, Westminster, S.W.—Two Attending Medical Officers.

WISBECH, NORTH CAMBS. HOSPITAL.—Resident Medical Officer. Salary £100 per annum, with rooms, attendance, coals, gas, and washing.

WOLVERHAMPTON AND STAFFORDSHIRE GENERAL HOSPITAL.—House Physician. Salary £100 per annum, with board, lodging, and washing.

THE Chief Inspector of Factories, Home Office, S.W., gives notice of vacancies for Certifying Surgeons under the Factory Act at Wigton, in the county of Cumberland, and at Newtown, in the county of Montgomery.

Births, Marriages, and Deaths.

BIRTHS.

BENNETTS.—On Oct. 14th, at Bozeat, Northants, the wife of F. Bennetts, M.R.C S., L.R.C.P., of a daughter.

DEAN.—On the 19th inst., at Eversleigh, Banwell, Somerset, the wife of the late Andrew Buchanan Dean, M.B., C.M., of a daughter.

FOOKS.—On Oct. 17th, at the New Infirmary, Isleworth, the wife of W. Pemberton Fooks, M.A., M B. Cantab., of a son.

ROSE.—On Oct. 14th, at High Beach-road, Loughton, Essex, the wife of Percy Rose, L.R.C.P. Lond., of a son.

MARRIAGES.

PEARSON—JONES.—On Oct. 15th, at All Hallows Church, Ordsall, Retford, George Bruce Pearson, L.R.C.S., L.R.C.P., of Buckingham, to Maud Mary, only daughter of the late Samuel Jones and of Mrs. Jones.

WILSON—WRIGHT.—Oct. 14th, 1903, at St. Michael's Church, Markington, by the Ven. Archdeacon A. S. Aglen of St. Andrews, assisted by the Rev. S. A. Brooking, Vicar, Alex. Garrick Wilson, M.A. Camb., F.R.C.S. Eng., of Ranmoor, Sheffield, eldest son of J. Mitchell Wilson, Esq., M D., of Cottingham, to Mary Evelyn, third daughter of the late Dr. J. Hodgson Wright and of Mrs. Hodgson Wright of Kirby Leas, Halifax.

DEATHS.

HUTCHISON.—At Cradock, South Africa, on Oct. 13th, Robert Fergus Hutchison, M.B., C.M., D.P.H., aged 28, dearly loved son of Thomas and Nicola Hutchison, West Cults, Aberdeenshire.

STURGES-JONES.—On Oct. 21st, at The Willows, Chichester, Charles Sturges-Jones, M.R.C.S., L R C P., second son of the late Rev. Edward Jones, Rector of Milton Keynes, Bucks, in his 81st year.

TALLERMAN.—On the 17th inst., at the Langham Hotel, Portland-place, Lewis A. Tallerman of 50, Welbeck-street, aged 58.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

THE DIABETIC INSTITUTE AND THE DIABETES FLOUR COMPANY (INCORPORATED).

A CORRESPONDENT has forwarded to us a circular letter, a form of application for shares, and a prospectus which he received from the Diabetes Flour Company, the address of which is 15 and 16, St. Dunstan's-hill, London, E.C. The circular is marked "Private and confidential" but [illegible] contents public. [illegible] public but only [illegible] chemists. The subscription is offered not so much in order to procure by its means any additional capital for the sanatorium to be acquired but rather to make the members of the two professions, "on whose goodwill the success of our business entirely depends," profitably interested in the business and to secure their permanent coöperation by letting them share in the benefits to be derived from the growth and success of the company. As a special bonus, therefore, one founder's share of the value of £5 in proportion to every five debentures subscribed is offered. The circular goes on to state that the profits of the company have averaged during the last three years 23 per cent., and further the circular says that "the company, assisted by the coöperation of physicians and chemists, will, we are convinced, pay still larger dividends in the future." The prospectus gives an account of a mansion situated in Kent which is to serve as a sanatorium for the treatment of diabetic subjects. We consider this circular to be a direct insult to the members of the profession of medicine. It is neither more nor less than a bribe to induce medical men to tell their diabetic patients to buy the products of the Diabetes Flour Company; but yet worse remains behind. We have also received from another medical correspondent a letter in which he says: "The inclosed is the third communication from the same source that a patient of mine has received since obtaining starch-free foods from a London firm." The inclosure to which he refers is headed "The Diabetic Institute," of which the address is "St. Dunstan's-hill," the chief analyst is Professor Dr. E. D. Berghaus, the president is Henry S. Berry, the manager is E. E. Naegelen, and the secretary is W. Norris. Curiously enough the names of these gentlemen, with the exception of Mr. Naegelen, appear as holding the same offices in the Diabetes Flour Company, except that Mr. Berry instead of being called "president" is called "the chairman of the board of directors." This being so, we presume that the Diabetic Institute and the Diabetes Flour Company are one and the same commercial concern. Their telephone number is the same and their cable address is the same. The Diabetic Institute, however, boasts a chief consultant whose name is Dr. Aston-Davis and the letter which was sent to our correspondent's patient commences as follows:—"Dear Sir,—We have twice written to you calling your attention to the seriousness of diabetes and placing the services of the Institute at your disposal, but up to now have received no reply to all our communications." The letter goes on to say that advice is given gratuitously and finishes as follows: "What we have done for others we can do for you and any correspondence that may pass between us will be treated as strictly private and confidential. Will you please let us know what is the reason of your silence so that in case you do not need our services we may take you off our mailing list." This letter is signed "W. Fripp" or "Tripp," "secretary," although in the printed heading the secretary's name is given as "Norris." It is perfectly evident from these documents that the Diabetes Flour Company and the Diabetic Institute form a purely commercial speculation which endeavours to widen its business by attempting to bribe medical men and pharmaceutical chemists and by writing letters to patients suffering from diabetes which may frighten them into applying to the Institute for advice. Our contemporary *Truth* has already made some scathing remarks upon this concern and in its issue of Oct. 15th prints a copy of a postcard *which has been addressed to chemists throughout the country.* The postcard which is headed "The Diabetes Flour Company, 15 and 16, St. Dunstan's-hill," is as follows: "We pay 5*s.* for every address you may be able to procure us of persons suffering from diabetes. These addresses will be used for the mailing of our new catalogue and your information will be considered as strictly confidential. It is money easily earned." It would be interesting to know whence the Diabetic Institute obtained the knowledge that our correspondent's patient was suffering from diabetes unless it was communicated by someone in the employment of the diabetic-food-providing firm. Dr. Aston-Davis has, we presume, an American qualification; any way, we cannot find him in the current number of the Medical Register. Moreover, the factory of the Diabetes Flour Company is at Watertown, New York. Four of the directors are connected with New York firms and the fifth is a manager of the London branch of the Anglo-American Bank. American commercial methods may be "smart" but we do not like them as applied to medicine.

MOTOR-CARS FOR MEDICAL MEN.

To the Editors of THE LANCET.

SIRS,—In THE LANCET of Oct. 10th you invite replies to your correspondent signing himself "General Practitioner" on the above topic. I therefore hope that the following observations may be of assistance to "General Practitioner" and others who are thinking of investing in a motor-car. For the last 13 months I have used a small petrol car with the greatest satisfaction [illegible] exceptionally hilly with a notoriously greasy surface after rain, the latter a most adverse factor in motoring. The pleasure of driving even a small car oneself is very considerable and the great saving of time effected by the use of a car and the fact that it is at all times instantly available are desiderata of much importance to medical men. As to reliability, a good modern car is at least as dependable as a horse. The cost of upkeep, including initial purchase money of a petrol voiturette, is probably less than that of a single horse and carriage. A plan I would recommend to "General Practitioner," if he be in the habit of keeping two or more horses, is to sell these and to buy two small cars of well tried make [illegible] With these [illegible] ther always [illegible] more than equal to any work he may require of it, it will occasionally happen that he is temporarily without a car owing to renewal of worn working parts, such as bearings, gears, tyres, &c. The cost of two small cars will not exceed that of a single car of twice the horse power with two or more cylinders, whilst they are as efficient for the purposes of a medical man as a larger car. Moreover, the cost of running a small motor is much less than one of medium or large power, pneumatic tyres largely accounting for the difference. Medical motorists may be grouped into two classes: (1) those without any mechanical instincts or inclinations—they will have to employ a skilled driver and this will, of course, add to their expense; and (2) those, at present by far the most numerous class I believe, who taking a keen interest in their [illegible] more often due to some oversight of themselves. The latter class will only need to employ unskilled labour in the form of a lad or former coachman to clean the car, accompanying them on their rounds, and start the engine after a stop. Some form of non skidding device attached to the rear or driving wheels is very desirable in winter. I am not an advocate of any special form of protection from the weather in the shape of a hood or screen. A good motoring coat which can, if desired, be worn over an ordinary top-coat is, as far as my experience goes, all that is required. This should be obtained from a firm who make a speciality of this particular garment, since the usual mackintosh by no means meets the requirements of a motorist. I think that all, or nearly all, those medical men whose circumstances and temperament enable them to be grouped into class 2 will bless the day that they adopted a motor-car. I am here obviously premising that class 2 will select their motor car with judicious discrimination, having regard to their individual requirements.

I am, Sirs, yours faithfully,

Torquay, Oct. 19th, 1903. GILBERT J. ARNOLD.

PLASMON TEA.

To the Editors of THE LANCET.

SIRS,—Your analytical report of this preparation suggests the query whether the tannin in ordinary tea prepared in the usual way is not more completely precipitated and rendered as physiologically inert by the addition of a small quantity of milk. This milk tea is very palatable to many people and is certainly more economical than plasmon tea.

I am, Sirs, yours faithfully,

Oct. 19th, 1903. SIMPLEX.

*** [illegible] red to have the same effect [illegible] to the tea, since plasmon [illegible] s weight of milk, and the separation of tannin in plasmon tea is undoubtedly more effectual and complete than when milk *alone is used.*—ED. L.

THE CIGARETTE CRAZE.

To the Editors of THE LANCET.

SIRS,—With regard to the letter of "Doubtful" upon cigarette-smoking in THE LANCET of Oct 17th and your comments thereon may I suggest that the quantity as well as the quality of the tobacco consumed by cigarette smokers may be a factor in such results as may follow? "Doubtful" writes of "excessive cigarette smoking" being responsible for nerve trouble and then goes on to say that a man who smokes nine or ten cigarettes in a day does not smoke half an ounce of tobacco. I should have thought that a man who smoked cigarettes to excess smoked far more than nine or ten in a day, but that a man who smoked half an ounce of tobacco per diem in a pipe was a fairly heavy smoker. To put it in another way, the tobacco that will make a good sized cigarette will amply fill a good-sized pipe, but if one man smokes cigarettes during the time that another *consumes one pipeful* of tobacco he will get through considerably more than one cigarette. There are reasons for this. The burning surface of a cigarette may be smaller than that of a pipe but the smoke passes through a tube (at all events where no mouthpiece is used) which is considerably larger than the bore of a pipe and the rapid burning is not diminished by the tobacco of a cigarette being usually very dry. The inhalation of a cigarette is almost irresistible. I doubt if confirmed cigarette smokers would derive any satisfaction from smoking if they were merely to take the smoke into their mouths, and I expect that in this you have named the principal cause of the effects produced by excessive cigarette smoking, but it would be interesting to know your views as to what amount of tobacco is consumed in cigarettes by those who suffer from its effects. I fancy that average sized cigarettes run to about 16 to the ounce and that this would be a moderate allowance to some smokers in the day. "Doubtful" speaks of very mild tobacco being hot in a pipe. Does not this depend largely on whether it is fine-cut or not? I smoke a very mild tobacco, which is coarse-cut, and to me, at all events, it is not hot, but a mild tobacco is often very fine-cut and consequently liable to get dry and to burn fast or, at all events, to burn hotly. In the same way fine coal, with a good draught, burns with great heat. I am, Sirs, yours faithfully,

Oct. 19th, 1903. E. A. A.

THE BY-LAW AGAINST SPITTING.

THE prompt enforcement of one of the London County Council's new by-laws at the Westminster police-court must have come as a severe shock recently to a man named Richard Donovan. He had persisted in spitting in a tram-car in the Wandsworth-road and had continued to do so upon being cautioned by the conductor, besides being abusive and refusing to quit the car. The evidence of the conductor was supplemented by that of a passenger who had had to move from his seat in order to avoid being spat upon. Two summonses were taken out by the County Council, one for spitting and the other for using obscene language, and Donovan was fined the full penalty, 40*s.*, on each, with costs, the total amounting to £6 2*s.*, with the alternative of a month's imprisonment. His fate should serve as a warning to others and as a protection to future travellers, while it will materially strengthen the hands of conductors of public vehicles and similar officials. An amusing story, by the way, has been told of a tram conductor in Dublin. An elderly lady from England travelling upon his car was much disturbed by the free expectoration indulged in by a passenger near her. Turning to the doorway she asked nervously, "Conductor, do you allow spitting upon your tram-car?" Mistaking her meaning the conductor, with bland politeness and a rich brogue which the reader must reproduce for himself, answered, "Certainly, madam; spit wherever you please."

PATHOLOGICAL PARLANCE.

THE Dean of Bristol, the Rev. Dr. Pigou, in a further volume of his reminiscences which has just been published, tells several good stories, amongst which is the following. A lady when leaving her house on the way to Divine service had omitted to take her reticule, or hand-bag, such as ladies carry. Her maid, in reminding her of this, said: "Please, ma'am, you have forgotten your appendicitis!"

SUBSTITUTION RAMPANT.

To the Editors of THE LANCET.

SIRS,—Your annotation headed "Substitution Rampant," in THE LANCET of Oct. 17th, p. 1104, seems to me to be of peculiar importance to those members of the public who are in the habit of purchasing the goods of well-known and old-established firms because their staple quality and permanence of value may be relied upon.

I have, rightly or wrongly, an old-fashioned prejudice in favour of being supplied with exactly what I ask for, whether it be a food, a drug, a sauce, or a wine. It is most annoying to be told by otherwise reputable retailers that their own produce is as good as, or better than, what you have asked for. The reason of this attempted substitution is doubtless the opportunity of greater profits, but this has nothing to do with me as a regular purchaser who consistently buys certain brands and has no desire to experiment with imitations.

Your suggestion in connexion with a recent case of a pair of so-called solid leather boots, which were found to contain cardboard soles, seems to me to be excellent. There ought to be some system of control over such a deliberate fraud. Perhaps an existing Act could be so extended as to cover this, or in default a new Act framed expressly to protect the purchaser from such deception on the part of the seller.

If the different trades could combine among themselves and each decide upon some mark of guarantee, answering to the hall-mark on silver, thereby insuring the honesty of their goods, I am certain it would be of immense service both to themselves and to the public. I inclose my card. I am, Sirs, yours faithfully,

Oct. 19th, 1903. F. S.

To the Editors of THE LANCET.

SIRS,—Your annotation under the above heading in THE LANCET of Oct. 17th, p. 1104, directs attention to, and very justly condemns, the vast amount of fraud which pervades a great deal of our present system of trading and which flourishes unchecked under the supine methods of control exercised by the authorities of the State. This deplorable and criminal lack of business morality, moreover, touches very closely a subject which is of the utmost interest and importance to the medical profession. I refer, of course, to the question of the purity of drugs and of accuracy and honesty in dispensing. There is no department of trading which calls for the exercise of more care and more scrupulous honesty than the manufacture and dispensing of drugs and there is no department of trading in which fraud is more difficult of detection. Yet I venture to suggest that substitution and adulteration are as rampant in this branch of commerce as in the others to which you have called attention. In these days of "store prices" and of "prescriptions carefully and accurately dispensed" the operation of the hall-mark you suggest would prove of inestimable service both to physician and to patient.

I am, Sirs, yours faithfully,

Upper Berkeley-street, W., Oct. 21st, 1903. E. H. COLBECK.

*** We may point out that our correspondent's view in regard to the accurate making up of prescriptions receives little support from an inquiry which we instituted upon this subject, the results of which were published in THE LANCET of May 2nd, 1903, p. 1251. Prescriptions, moreover, are subject to control under the Sale of Food and Drugs Act.—ED. L.

LIFE INSURANCE FOR HIGH RISKS.

To the Editors of THE LANCET.

SIRS,—Can any of your readers inform me as to assurance companies which would consider proposals on the lives of persons proceeding to the West Coast of Africa, Nigeria, &c.? I have tried four companies without success. I am, Sirs, yours faithfully,

Oct. 20th, 1903. CROSS.

A CONVENIENT SUBSTITUTE FOR A SAND-BAG.

To the Editors of THE LANCET.

SIRS,—Whilst casting about for a substitute for the weighty sand-bag I recently hit upon the following which may be useful to those of your readers who are called upon to perform operations which involve the use of a sand-bag The bag is similar in composition to the fenders of a yacht's boat—i.e., it is made of canvas and is filled with cork dust. The result is a bag which combines lightness, firmness, and cheapness. I have used such a bag while operating on the bile-ducts and have found it to answer admirably. A cylindrical bag 20 inches in length and 15 inches in circumference weighs 31 ounces and costs 1*s.* 9*d.* The bag can be covered with mackintosh as is frequently done in the case of the ordinary sand-bag. I am, Sirs, yours faithfully,

Plymouth, Oct. 19th, 1903. C. HAMILTON WHITEFORD.

◆

Nook.—We should think that our correspondent would find all the information which he requires in the volumes dealing with insects which form part of the Cambridge Natural History published by Messrs. Macmillan and Co.

Syntax.—We do not think that our correspondent need have any fear of the General Medical Council regarding his connexion with the dispensary in question in the manner which he suggests.

Mr. T. Laffan.—The Tallerman Institute, 50, Welbeck-street, W., and the Dowsing Radiant Heat Company, 24, Budge-row, Cannon-street, E.C.

A Student.—Our correspondent has omitted to inclose his name and address.

Medical Diary for the ensuing Week.

Therapeutics

NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC (Queen-square, Bloomsbury).—3.30 P.M. Dr. Tooth: Localisation in the Spinal Cord.

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

The rates of subscriptions, post free, either from THE LANCET Offices or from Agents, are:—

FOR THE UNITED KINGDOM.		TO THE COLONIES AND ABROAD.	
One Year	£1 12 6	One Year	£1 14 8
Six Months	0 16 3	Six Months	0 17 4
Three Months	0 8 2	Three Months	0 8 8

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, MR. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE. It has come to the knowledge of the Manager that in some cases higher rates are being charged, on the plea that the heavy weight of THE LANCET necessitates additional postage above the ordinary rate allowed for in the terms of subscriptions. Any demand for increased rates, on this or on any other ground, should be resisted. The Proprietors of THE LANCET have for many years paid, and continue to pay, the whole of the heavy cost of postage on overweight foreign issues; and Agents are authorised to collect, and do so collect, from the Proprietors the cost of such extra postage.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied. Address—THE MANAGER, THE LANCET OFFICES, 423, STRAND, LONDON, ENGLAND.

METEOROLOGICAL READINGS.

An original and novel feature of "THE LANCET General Advertiser" is a Special Index to Advertisements on pages 2 and 4, which not only affords a ready means of finding any notice, but is in itself an *additional* advertisement.

Advertisements (to ensure insertion the same week) should be delivered at the Office not later than Wednesday, accompanied by a remittance.

Answers are now received at this Office, by special arrangement, to advertisements appearing in THE LANCET.

The Manager cannot hold himself responsible for the return of testimonials, &c., sent to the Office in reply to Advertisements; copies only should be forwarded.

Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Office, 423, Strand, London, to whom all letters relating to Advertisements or Subscriptions should be addressed.

THE LANCET can be obtained at all Messrs. W. H. Smith and Son's and other Railway Bookstalls throughout the United Kingdom. Advertisements are also received by them and all other Advertising Agents.

Agent for the Advertisement Department in France—J. ASTIER, 31 Rue Bapts, Asnières, Paris.

A Lecture

ON

THE MENTAL DISEASES OF THE CLIMACTERIC.

Delivered at the Medical Graduates' College and Polyclinic on March 12th, 1903,

By GEORGE H. SAVAGE, M.D., F.R.C.P. LOND.,
CONSULTING PHYSICIAN, IDIOT ASYLUM, EARLSWOOD.

GENTLEMEN,—The mental disorders of the climacteric constitute a subject which one would have thought would have been very largely and generally handled not only by the alienist but also by the gynæcologist. It has really been very imperfectly dealt with until comparatively recently. It has appeared to be a sort of No Man's Land not to be cultivated. Yet the more one sees of the influence of the climacteric the more is one impressed with the very grave importance of it, first as a cause, or one of several associated causes, of mental disorder and next, and perhaps this is more important from a practical point of view, as to its influence in prognosis. I have, I believe, mentioned elsewhere that of youth it is a common thing to hear the friends say: "Here is a young patient with mental disorder of one kind or another, but youth is on his side." And I have been obliged to say: "No; youth is not always on the side of the neurotic." There have been some, relying chiefly, I believe, upon general experience or what appears to be common sense, who have said: "Surely, with this climacteric case there will be a favourable prognosis." Certain patients have been nervous in development, they have been hysterical, they have suffered from puerperal insanity, they have had forms of insanity of one kind or another dependent perhaps even upon toxic causes, "Surely," it is said, "when these have passed the climacteric they will be all right." That is a common idea, especially in relationship to puerperal cases. Here is a woman having children, and having attacks of puerperal mania, suffering from attacks of insanity associated with pregnancy. When the period of childbearing is over surely there will be no more danger. Unfortunately that is not my experience I find that those who are predisposed to break down along nervous lines, who have perhaps had attacks of insanity, are much more likely to break down permanently at the climacteric. Another thing I shall have to point out is that with the climacteric you do not get, or you very rarely get, a clearing away of the nervous disorder. This fact has been, and is constantly being, brought before me: here is Mrs. So-and-so who has been more or less of an invalid nervously all her life; she has been suspicious and troublesome at home with her hypochondriacal symptoms: "I suppose," say her friends, "that as soon as she has passed the climacteric we may hope that the mental symptoms will pass off?" but they do not pass off.

Now to consider in detail the symptoms which may arise—that is to say, nervous or mental symptoms—in connexion with the climacteric. And I would say that we have to recognise a climacteric in men as well as in women, though it is not so evident. I have sometimes said that retiring from business and ceasing to menstruate seem to be equivalent in the two sexes, that the same sort of disorder that is seen in a man who has given up active work may be met with in the woman who has ceased to menstruate At any rate, the climacteric has a very definite influence, more particularly, of [illegible] ffect is clearly observable even [illegible] n who have had any general [illegible] are associated with it. Some of these symptoms and nervous exaggerations I shall refer to later, but under ordinary conditions you find that there are a fulness of the head, a sleeplessness, and a malaise. I sometimes say that just as we have morbid growth developing physically so we may have mental morbid growths developing just as clearly and that such symptoms may be accentuated or revealed by the climacteric. Even with the most ordinary symptoms there is a change—and a very material change—often to be observed at the climacteric and this is more marked in those with strong hereditary neurotic tendencies. No doubt the neurotic by inheritance are much more liable to break down at this period than those who are free from neuroses. Then, again, the climacteric is especially dangerous to those who have had previous attacks of insanity, whatever the cause of these previous attacks. Next, you may have neurotic disorders depending upon the on-coming climacteric. One may be asked for how long a period do you posit the influence of the climacteric and I am obliged to admit that the cases I have come across, and which I am about to describe and to group under the heading of climacteric cases, not infrequently occur a year or even more before the cessation of menstruation. Probably many of you know, much better than I do, that in some subjects the menopause comes on almost suddenly, while in others there is a warning for a year or two, or even for three or four years previously. It is a common experience of mine to find an irregularity of menstruation, excessive menstruation, perhaps, with flushing of the face and a feeling of heat and of sleeplessness, and dyspepsia, and general unfitness for some years before the menstruation ceases. Now and then there are neuroses starting at that time. Take an example. A woman, three or four years before menstruation ceases, has irregularity of menstruation. First there is a cessation; she gets into a dreadful state of alarm, thinking she is pregnant; she thinks there is a late pregnancy and she worries about it and becomes sleepless and out of health generally, often, indeed, hypochondriacal or melancholic. The menstruation reappears, this time rather profusely. She loses for the time her melancholia. Then when another year or two have passed her menstruation, which has been in the meantime irregular, now ceases and she recognises that it has gone, but there comes a disorder of a different type. She believes that she has changed, that she is unnatural, that her husband no longer cares for her, that her children look upon her with suspicion, and that her neighbours avoid her. Thus the first nervous symptoms are associated with the first irregularity in connexion with menstruation, and the fully developed insanity is usually associated with the completion of the menopause. Of course, in the majority of cases the insanity associated with the climacteric is coincident with the other symptoms, with the immediate cessation or the irregularity of menstruation, with, in fact, the ordinary symptoms of the climacteric. In other cases, which can scarcely be classed under the same head, we get the menstruation ceasing altogether and mental disorder following after a considerable interval. I saw a case recently in a woman who had ceased to menstruate. She had had the ordinary symptoms of a slightly exaggerated type; she had had nervous breakdowns before; she had been self-indulgent and hypochondriacal; she thought she could no longer do this and that and the other. She had ceased to menstruate for two years and it was more than a year after the cessation before the sleeplessness from which she had always been a sufferer became so marked as really to produce serious mental disorder. Then she believed herself to be no longer an agreeable person to her relatives and her friends; she regarded herself as a devil and concluded that the best way of getting rid of that devil was to take a considerable dose of poison. It was in those circumstances that she came before me.

I may now ask—At what age does one generally meet with persons suffering from climacteric insanity? Well, there are some cases which come on early and others later. I see cases occasionally in which the climacteric insanity comes on very early. Now and then one comes across a case of a woman who ceases to menstruate soon after she is 30 years of age and it has been my chance to see a case in which both ovaries were removed even at an earlier age than that, and in such cases the patient may develop a surgical climacteric disorder. In fact, you may find these disorders occurring after removal of the ovaries at almost any age. You may have insanity coming on in people who have ceased to menstruate prematurely but the majority of women cease to menstruate at between 45 and 50 years of age One can hardly say that there is any one particular time which is more dangerous in this respect than another as far as surgical interference goes. Another important question, Is there more danger with single or with married women or with widows? Looking through the records of many hundreds of cases which I have had under my observation I have found that the proportion of single women so affected is greater than that of married women and that, comparing the number of widows with married women in the population, there is undoubtedly an excess of insanity associated with the climacteric in the former. In fact, I have sometimes described it as a widows' disease or a widows' disorder. I shall have to refer to that again later.

Now as to collateral causes, it being assumed that the cases which we are considering have as their exciting cause the climacteric. We have seen that neurosis is a very important factor. We have seen that no actual age can be assigned as the culmination of the dangerous influence, that more single than married women suffer, and that more widows than married women break down in this way. But now comes a very important practical point—viz., the very large proportion of cases of climacteric insanity associated with alcohol. The number of women who take to alcohol and bring on alcoholic troubles at or about the menopause is quite astonishing. There is at that time this feeling of "sinking," this languor and inability to do what they would, and then there is the taking of a little "pick-me-up" occasionally. And in this way you find women at that time of life taking not only alcohol but drugs. Many a drug-taker has come before me who has taken chloral and even paraldehyde in large doses simply as the result of the restless, miserable feeling associated with the menopause. Alcohol is one of the most important collateral causes of mental disorder during the menopause.

To take the clinical forms of disorder which one is likely to meet with, it seems to me a natural way to take first the mere exaggerations of the ordinary clinical symptoms of the climacteric and also the exaggerations of the temper of the individual. With the climacteric you not infrequently get an insane interpretation of the physical symptoms. For instance, a woman who has got flushing associated with the menopause says: "I am blushing, and people look at me, and they think there is something I am ashamed of." There is nothing of the sort. She has simply got a feeling of flushing which she misinterprets and it slowly develops into delusions that people are watching and following her, looking after her and scandalising her and taking away her character, and the like. And so this simple symptom may tend to create an exaggerated susceptibility the foundation of delusions. In the same way there is a sensation of fulness in the head. The woman says: "There is something wrong with my brain; I have got cancer there." I recently saw a female patient who had had cancer removed from another part of the body. At the climacteric she complained of fulness in her head and she was sure that she had got a cancerous tumour there, another insane interpretation of what may be called an ordinary climacteric symptom. An unnatural feeling about the skin not infrequently gives rise to the idea that there is something wrong with it. One lady declined to shake hands because she vowed she had the itch; another declined to go near people because with these uneasy feelings about the skin she felt sure she had small-pox. In another, and a still more difficult case, the patient believed that these uneasy feelings in the skin, associated as they were in her case with hallucinations of smell, were associated with syphilis, syphilis which she felt sure her husband must have given to her. So you see the whole growth of a delusion which not only implicates herself but her husband also, there being no truth in the accusation. She knew that she had no other way of catching syphilis and concluded it must have come through her husband. With these sensations there is often a sense of change which is very marked and characteristic; the patients feel they are no longer human One said: "Look at the hair growing on my face. That is not womanlike—in fact, I do not believe I am an ordinary woman I think it is a disgrace; I cannot expect my husband to love a woman with hair on her face; I am no longer a woman, I am no longer attractive; my children no longer can like and love me. How can a child kiss a mother with a beard? It is disgraceful, and the sooner I am dead the better." I have known cases of that kind. I have also found myxœdematous conditions associated with the climacteric and this has given rise to a double set of symptoms of mental disorder, a somewhat parallel causation. First the individual, looking changed in aspect owing to myxœdema, says, "People make remarks about me and say there is something wrong with my face." Or others at the climacteric who develop myxœdema and get ideas that they are not like other people, that they are inhuman. With the climacteric you may get, as I have said, exaggerations of any one of these symptoms depending upon a collateral causation or upon the climacteric itself. I mentioned in my last two lectures that in relationship with sexual disorders of one kind and another you frequently get hallucinations of smell and that these conditions frequently give rise to more or less fixed delusions. I referred to "syphilitic" delusions and also to the ideas of being chloroformed and robbed. All these and many similar states are subject to the more or less considerable accentuation of the change occurring in the reproductive organs at the climacteric.

From the mere false interpretation of physical symptoms at the climacteric I shall now pass to the change or accentuation in the temperament of the individual. Take an example. It is a woman who has always been a careful, economical housekeeper. She arrives at the climacteric and becomes a terror to herself. Everything is exaggerated. A speck of dust becomes a mountain of mud. She is restless, she is here, there, and everywhere upsetting everything and everybody. I have had men come to me saying, "Is my wife mad, or what is wrong with her?" I say, "What is wrong?" "Well I go home and find all the servants have been discharged and all through the most trifling thing, too. She says this has not been properly cleaned and she appeals to another servant who says it has been cleaned and then she discharges the lot." The unfortunate husband suffers grievously under such conditions as these. I have seen such a woman who has been taken before a magistrate and sent to prison for bullying and ill-treating her servants. Such people are to be pitied and all those connected with them, for in the above case, for example, the unfortunate woman was without doubt suffering from an exaggerated dust and dirt consciousness, so to describe it, bullying her servants and losing her temper, striking them, and not feeding them properly. Such a woman will say, perhaps, "If you do not keep my house clean I shall not give you food." All this is an exaggeration of temperament, so to speak. In the same way one gets an exaggeration of self-consciousness—a real hypochondriasis. For example, an individual who has been pampered and allowed to do very much as she likes, who never dreams of getting up to breakfast, gradually gets more and more self-indulgent till she may, as in several cases I have seen at the climacteric, become a chronic hysterical paraplegic, or she loses her voice, or becomes so hyperæsthetic that the slightest touch makes her scream. She will not allow her hair to be brushed or have anything done for her. This is an exaggeration of the self-conscious feeling which has been part and parcel of her nature; the accentuation is due to the climacteric. Then you get another kind of case which often causes great trouble to the husband, nor is it such a very uncommon kind of case either. The woman thinks something is going to happen to *him*. One man appealed to me and said, "What am I do? I live so many miles out of town and I come to my office every day. In the middle of the morning my wife puts her head in at the door and says, 'Oh, it's all right is it? I got so anxious about you after you left; I thought some accident would happen to you.'" She may go home to luncheon and come back before the evening to be quite sure that all really was right. This woman had always been an anxious-minded person. Again, I have seen children positively injured through the exaggerated care of a climacteric mother or some change in her. Some women who have been quick-tempered, for example, become incorrigibly violent tempered. And one is not uncommonly consulted about cases in this way. A man says, "I do not know whether I ought to consult you or my solicitor." "Why?" "Well, my wife is simply intolerable; she makes my life miserable. I come home and I say, 'What are you going to have for dinner?' and she immediately flies into a temper and says, 'As if you cannot trust me to arrange that. You are always grumbling about dinner,' and then she rages and dashes out of the house. She turns up again an hour or so afterwards in a more reasonable frame of mind. But on another day the passion and rage come on again." Fortunately some of the symptoms may pass off with the climacteric or its waning influence. But in many cases, as I pointed out in the beginning, they do not; in some cases the excitement becomes so marked that it may lead even to homicide, infanticide, and suicide. The subject says, "I will not stand it any more" and she rushes out and drowns herself. I fear that is quite a common sequel. There is another, certainly most annoying, development which you will perceive to be a natural association with the function of reproduction—namely, amorousness. These cases are really dreadful. I had a medical man in my consulting room this morning with such a lady and her husband. The medical man applied to me by telephone to know what was to be done Here was this lady who had been pestering him for a considerable time and yesterday she appeared at his house, which is not very far from my own, and tried to get in. He on his part, knowing that she was about, kept a chain on the door. She raves at him through the door, a mob collects, two policemen are sent for, and I was going *to say the character of the gentleman is involved, there* being absolutely no ground for it. Then comes the husband: "It is not only Dr. So and-so," says he, "but if he is out of the way it is one of my hunting friends." The woman is 52 years of age and is passing through the climacteric and there is alcoholic indulgence as well. Such cases as those are very dangerous indeed. They make terrible accusations and their chief victims appear to be medical men and parsons I shall refer specially to them later Here I may *point out that correlated with amorousness* you get, and very naturally, jealousy. One of my favourite examples was that of a woman whose whole life was something of an idyll. An artisan of the good honest type falls in love with a milliner's assistant of good looks and capacity. They say: "When we have got just enough money we will marry. We will work together and keep no servants." He says: "I will have a little shop for you and I will do my mechanical work downstairs"—he was a mechanical engineer—"you will keep house, and we shall only want two rooms." They do marry. She, regarding herself and her feelings, gets up at four o'clock in the morning to clean the windows so that the neighbours shall not see her do it and know that she does not keep a servant. They are fairly successful and look forward to a house in the suburbs, where they will live and will then keep a servant. So eventually they get a pretty little house in a suburb with four or five rooms, nicely furnished *en suite*, gold and white being the characteristic ornamentation. The whole thing is ideal. But the husband becomes more occupied; he does not come home to lunch and he does not come back to tea, and later he does not come back till supper There is no family; she is a childless woman. At the climacteric there comes the idea: "My husband is neglecting me; he might come home. Which way does he come? He comes George street way, why should not he come John street way? That seems nearer." She inquires and finds that there is a woman who has had an illegitimate child in George-street and she is quite sure that her husband must be the father of that child She dwells upon this till she makes up her mind to put an end to it. I saw her husband after she had "put an end to it" She had destroyed his clothes, smashed the presentation clock, she had smashed everything which was smashable in the house; she had taken the carving knife and cut the *stair carpet from end to end,* and had *written on the* drawing-room paper, "Go to your whore!" She was sent to an asylum. On passing through the climacteric she got well.

I have before me a somewhat similar case in a professional man whose wife helps him, typewrites his letters, and so on. Here again the wife is a childless woman. With successful progress has come the need for employing proper assistants, clerks, and so on. His wife has no occupation now. *She is no longer wanted where she was before.* She develops jealousy, suspicion, and thinks there is somebody else replacing her. That is a very common form of disorder associated with the climacteric There is also the form of suspicion which is shown in what I may call the "blotting-pad cases," for I have not infrequently surprised persons by saying, "You wife looks at your blotting pads." It is one of the items of experience The woman is suspicious about her husband, thinks he is concealing things, and dealing *improperly where he ought not. She gets his blotting-pad* and puts it in front of the looking-glass She does this over and over again and at last she finds what she thinks is "My dearest" somebody, it is "dearest" with a blot, and she is satisfied. That is the tangible starting point of delusions of suspicion—the delusions of suspicion which not infrequently give rise to further perversion, for later comes the dominant idea, "He wants to get rid of me." A woman came to me some years ago. She was waiting in my room when *I arrived from dinner.* She *said,* "I *wanted to* see you very much." She had a black-bag and began bringing things out one after another. I knew what was coming. She said, "I want you to have this analysed. Look at my nose; do not you see the mercury coming through my nose?" I said, "No." "Well, then, take a magnifying-glass and look" She was sure that her husband had become tired of her. She "had a past" and she thought that her husband wanted to get rid of her and was poisoning her. The sequel was that he would not believe she was mad and later she cut his throat. It did not kill him but very nearly. He was not satisfied even then and next she burnt the house down That satisfied him and she is now in an asylum. In *all this bear in mind that I am referring to disorders* associated with the climacteric which are accentuations of the normal temper or temperament of the individual. Fortunately, a very large number of cases occur in which the symptoms are not so pronounced as those about which I have been speaking, but still serious enough to prevent any possibility of domestic happiness. I once wrote a paper mainly on such cases, entitling it "Marital Misfits" Unfortunately most of them do not settle down but remain incurable all *their lives.*

Now let us speak of more distinct forms of mental disorder to be met with about the climacteric First of all there are those associated with the defective control of which I have spoken, in which there are impulsive acts, passionate acts, or suicidal acts. Then come the defects of volition embodied in a state of doubt and inertia—that is to say, want of power. The contrast is striking and will bear repetition—viz, there are numbers of people at the climacteric who lose higher self-control and become passionate and impulsive, and so impulsive that they may be suicidal, while others lose the power of judgment and exhibit *folie de doute* in the most marked way, so that they can never make up their minds to do anything; they are thinking all the time what they *will* do and practically doing nothing. Some of these resemble a certain youth who was always trying to stimulate himself by good resolutions. He would say, "Now I will get up to-morrow morning at 8 o'clock and if not I will fine myself 5s" So one finds certain ladies who are going to begin "to-morrow" with their new method of management—and never do begin at all. The most serious cases of climacteric disorder are marked by defect of memory. One gets a certain number of these and it is noteworthy that among climacteric cases I have met 1 or 2 per cent. general paralytics in whom there is generally a marked progressive dementia as the chief feature indicating the onset of the disease as associated with the climacteric. Note also that with the climacteric you may have hallucinations of all kinds. Hallucinations of sight are very common; so are hallucinations of hearing, probably more common than those of sight. You have persons suffering from climacteric disorders who believe people are talking at or about them and they thus hear scandals about themselves, giving rise to further suspicions of one kind and another. As I have already mentioned there are frequently hallucinations of *smell and* taste and these may give rise to the idea of poison.

We are now beginning to see that there are various symptoms and delusions definitely associated with the climacteric We have seen that the suspicions relate more particularly to the husband, if husband there be. If the woman is single it is very common to meet with cases in which a woman conjures up an imaginary husband, she thinks that she has just been married, or that she has been *forsaken, or* that there is a man at the other end of the world who is being kept away from her. In the case of the widow you may find one of two very definite forms of delusion. One is that her husband is not dead. I have two at the present moment, both of whom decline to accept the statement that their husbands are dead. One was the widow of an officer and she declines to receive her pension because she believes that her husband is still alive. I have had one or two other cases of the same kind. *Such a patient* will say, "My husband has been taken away and they wish to make me take his pension so that I may acknowledge that he is dead and then they will bring him out of his hiding place and kill him." As a morbid development you get delusions of a sexual type that the husband is inconstant and neglectful. A woman will very frequently believe that someone is wishing to marry her and is prevented by foes, or she believes that she is married to improper people, demons, or Holy Ghosts. I have met cases of both. I see a fair number of spinsters at the climacteric who believe themselves to be on the point of bringing forth a Christ or some great prophet. There are also positive accusations of sexual offences. I suggest that you should always be on the look-out for dangers of that kind—false accusations, false confessions, and statements about syphilis, for at the climacteric it is not uncommon for a woman to say that she has been seduced by this or that person, and here also the extraordinary thing is that skeletons long lying dormant are galvanised into life. A woman of about 50 years of age, happily married, comes to the climacteric and says that she can only see me alone, that I must vow I will not tell anyone of her confession. Well, what is it? When she was 21 years old she was very much in love with a cousin and she rather thinks that she loves him still. At any rate, she is quite sure that she has been living for 30 years a life of moral adultery because of this penchant for her cousin. Confessions of that type are not infrequent and have to be taken with a very great amount of "salt." I should regard it as a case in point that if you have any reproductive organ disorder, or if you find a chance of that disorder, in hysterical girls with irregularity of menstruation, or suppression of menstruation, you often get statements that some old man has been taking advantage of them. We find the same sort of thing at the climacteric and wherever there is physical disorder of the reproductive organs there is the same risk. In the insanity which results you will find the same type of delusions, perhaps accusations against the husband in reference to syphilis and besides these disorders there may be moral perversions. I would refer in passing to the lying and tale-bearing which occur. Perhaps you will say that this feature also is only an exaggerated development of certain tendencies. It is, or it may be; assuredly one sees a certain number of those cases which cause infinite trouble by the development of the "lying spirit." Elsewhere when speaking of the insanities of development I pointed out that boys not infrequently, and girls often, took to lying naturally. There would seem to be a reversion type in some of these climacteric cases, a certain "romantic" lying associated with the confessions and accusations of which I have spoken. You will find a good deal of scandal-mongering, ingenious false letter-writing, sending of post cards, and so on. Every now and then I have a whole budget of post cards handed to me with, "What do you think of these?" They may be hysterical or they may be climacteric, they are commonly associated with one or other of these two states.

And now let us take from the medico-legal point of view one of the most difficult and interesting types—namely, kleptomania. Kleptomania is more commonly met with in the climacteric woman than in any others. In my younger days, when I was willing to appear in the police-courts, I not infrequently was asked to give evidence on behalf of kleptomaniacs—so-called. I should say that three out of four of them were women at the climacteric or women in whom there was some reproductive organ trouble if they were genuine cases of kleptomania. And I feel rather cowardly in not being still willing to attend these cases. But there is an odour about the police-court which one would prefer not to be in and one cannot help feeling inclined to avoid them, to say nothing of being looked upon as a bought witness and not only a paid one. Let me ask you, however, to remember that should you have to defend a woman who is accused of stealing uselessly or objectlessly, if she is at the climacteric it is a very important point in her favour. If there be hereditary neurosis or climacteric and drink in the case it is likely to be true kleptomania. But unfortunately drink, in the eyes of the court generally, had better be left out of the question. Among the moral perversions and lying commonly there are found all sorts of letter-writing persecutions, and here again unmarried women of from 40 to 50 years of age are the most common—I was going to say sinners, but I should rather say sufferers. I am speaking of individuals who write to parsons, who hunt parsons, who have hallucinations in regard to more or less conspicuous individuals. One unfortunate Nonconformist minister suffered a good deal. In two cases I had to take steps. In one case a lady was perfectly sure he wanted to marry her. I said, "He is married already." But she said: "No; that is all nonsense; he is going to marry me." She attends every Communion service on purpose to get near him. She goes to the Bible-classes to be near him. She watches at the hour he leaves the house and if he gets into an omnibus to go up to town she gets into the omnibus too. She writes amorous letters and makes this man's life practically intolerable. That is a type of disorder that is not uncommon. In one such case I got a woman sent back to her native country, but she came back to England again. Do not forget that these people go in for letter-writing without end and that no amount of persuasion or arguing is of the slightest use.

But I think you will have already perceived that disorders of the menopause are, in the greater proportion of cases, of a depressed type, melancholic, hysterical, with ideas of misery and persecution and watching. These are unhappy ideas and therefore it is not surprising to hear that it is very common to get as a result anything ranging from a simple lack of interest in life, a want of desire for life, to a feeling that they are in the way, that they cannot do as they like, that they do not feel as they should, that their husbands do not care for them, and that their children would be better without them, that they are avoided by their friends and acquaintances. All those ideas may coalesce and pass into a more definite and concrete melancholia. One has known a widow under such conditions simply to shut herself up and to decline to see anybody and to decline to have any but the plainest and simplest food—she said she was not worth more. A considerable number of these patients make an end of themselves, drowning perhaps being the most common means. On the other hand, one finds another type which is rather interesting from more than one point of view. With the expiry of the reproductive function there may be an accentuation of lust or desire or passion. It is not a very uncommon thing to meet with a climacteric-begotten child—that is to say, a case in which a child is begotten only a short time before the final cessation of menstruation. I have not infrequently seen women who have been pregnant just at that time become fearfully ashamed of themselves, they have sometimes committed suicide, or secluded themselves, or developed melancholia of the worst possible type, or they have accused themselves of being pregnant by the devil. They are quite sure it was an unnatural occurrence and that the offspring would be unnatural. Thus it is well to remember the wide diversity of melancholia at the climacteric and, remembering that with these patients you so often get a change in the physical state, you will find often a dry, harsh skin rather than that cold, clammy skin which you generally meet with in melancholia. And you may get a high-tension pulse I often wish I dared to bleed these patients; I find it is sometimes a good thing to reduce their diet and to give saline purges. They are sleepless and many patients do well with small doses of opium which seems to suit them better than anything else. One does not give opium as a rule in many cases of insanity, but in these cases especially, where there are melancholia and a restless agitated pulling and picking of the fingers, accompanied by a dry skin and rather full pulse, opium does very well indeed. As to the mania which is seen in climacteric cases it is generally a result of some abnormality in the reproductive organs and exhibits the eroticism, obscenity, lasciviousness, and various sense perversions of which I have given ample illustration. It is very common to find masturbation also. And you may find associated a period of loss of higher control, with eroticism accentuated and frantic masturbation followed by a reaction of extreme prostration and melancholia, with ideas of unworthiness and wickedness. These subjects will believe that they are very wicked and abandoned and no longer esteemed in respectable society because they have behaved so badly. In cases of this kind where there is considerable eroticism I give without hesitation large doses of bromide of potassium once or twice a day. I give a prescription of a drachm of the extract of salix nigra with half a drachm of bromide of potassium at night. That will often procure sleep and allay the erotic tendency. You do no good in these cases by local applications of cold. But I have found a sitz bath followed by applications of calamine powder to be useful. I have known cases in old days when the clitoris has been removed, but I cannot recommend this operation. In other cases it has been suggested that the ovaries should be removed, but in England we do not do this, though I believe it is done in America. Do not forget that in the cases attaining to mania also there is a great danger from drink. We have already seen that the climacteric is a period at which drink and drugs are most powerfully dangerous and are very readily taken to.

So far we have seen that there may be mania, melancholia, or progressive weak-mindedness, with loss of memory or general paralysis.. But next to melancholia probably the most common form, if not indeed more common than melancholia, is delusional insanity, with ideas of persecution. The self-conscious feeling associated with the cessation of the function of menstruation in patients leads to the idea that people are looking at them, that they are marked people, that people are saying something about them and following them about, watching them and saying something against them. One woman shuts herself up in her top room and covers all the windows with brown paper, completely shutting out the light, and she will allow her food to be admitted only through the door. I was shown into such a room and having struck a light I saw that there was no crevice through which light could come. The reason she gave for all this was that there were policemen at the opposite window watching her. Why? They said that she had been an immoral woman. Patients think their neighbours are taking away their character, they think they have procured men to stand outside their room or door to insult them, they think that these men are made to walk up and down opposite the house as decoys to get them out and then to say they have "spoken" to people in the street. A similar form of disorder is met with in widows. A youngish widow is left with an income of moderate amount and several children and has to live carefully and she has to be very jealous of her reputation and of what she does. When the climacteric comes she begins to think people are avoiding her. Her friends are dying; she seems not to be seeing so many people as she formerly did—which is a fact—and she is increasingly conscious of it She worries about this and thinks that her friends are constantly referring to her and that they are telephoning to one another about her. One finds these patients with delusions coloured by the latest invention and I have had some who think that others are sending Marconigrams through them or that they are being photographed while in their bath with x rays; in fact, that people are in every way annoying them under the belief that they are wicked. Unfortunately, a very large number of these delusional cases are unfavourable. Where you meet a woman with a fully organised idea of persecution which has lasted one or two years the patient will never get any better and the sense perversions on which such cases are built up may lead to all sorts of fancies about criminal assaults.

I must now say a few words about the influence of the climacteric on prognosis. Ordinarily one would say a case of acute insanity if the patient does not get well in a year, whether it is melancholic or maniacal, is a very unfavourable case. But there certainly are cases occurring at the climacteric about which you are justified in saying, "This case may last four or five years and yet get well." If the patient, however, has had attacks of hysterical or puerperal insanity, or, indeed, of any kind already, the prognosis is distinctly unfavourable and if the patient gets well she will probably be maimed intellectually and scarred morally. Then, again, as I pointed out at first, people will say, "Here my mother is suffering from insanity and has been for the last ten years but she is coming to the change of life; will there be any improvement?" I say, "No." What will be the result? Probably there will be no improvement and no change whatever. If the patient is showing signs of dementia at the climacteric it is almost certain that the dementia will become more pronounced afterwards than it was before. The climacteric in itself does not lead to, or tend to secure, recovery. Therefore you must not say here is a case of various attacks of insanity which is now entering or approaching the menopause and we are likely to have a period of rest and calm. It is not so.

The last thing I would say is this There is one problem which has never been solved I remember a case in which a woman at the climacteric committed adultery. I myself was perfectly certain that she was suffering from erotic mania associated with the climacteric. Is that plea a bar to divorce? The friends would not try it and so it still remains a question to which, as far as I know, no answer has been given.

WEST KENT MEDICO-CHIRURGICAL SOCIETY.—The following members have been elected as officers and council for the forty-eighth session, 1903-04:—President: Dr. Robert E Scholefield. Vice Presidents: Mr. G. Chisholm Williams and Dr. F. S. Toogood. Council: Mr. F. Septimus Barnett, Dr. J. H. Bryant, Mr. Charles J. Heath, Dr. H. A. Munro, Mr. William Henry Payne, Dr. H. Bowen Williams, and Dr. H. Leonard Williams. Treasurer: Mr. John P. Purvis. Secretary: Dr. John P. Henry. Librarian and Assistant Secretary: Dr. H. B. Kitchen.

A Clinical Lecture

ON

CARCINOMA OF THE COLON.

Delivered at St. Bartholomew's Hospital on July 3rd, 1901,

BY THE LATE WILLIAM J. WALSHAM, M.B.,
C.M. ABERD., F.R.C.S. ENG.,
SURGEON TO THE HOSPITAL.

GENTLEMEN,—In the wards there is a woman, aged 43 years, who was under my care something like 18 months ago with carcinoma of the colon. I removed that carcinoma and she made an excellent recovery. The specimen is in one of these bottles.[1] She then went out of the hospital and for about 12 months or so she was quite well. She has now got a recurrence in the pelvis and her case is rather hopeless. But it was an exceedingly encouraging case, because for 12 months she has been absolutely well without any trouble or any abdominal symptoms whatever. I thought this would be a good case to take as my text for a clinical lecture to-day and I therefore propose to talk to you upon the subject of carcinoma of the colon. And the better to put you into possession of the facts which I wish to lay before you and to emphasise I will treat the subject under the following heads and, like a sermon, I will divide it into three. My first proposition is that the common form of carcinoma of the colon—namely, the columnar-celled variety—is one of the most benign of the carcinomata. My second proposition will be this: that if the first proposition is correct the earliest possible diagnosis is of the greatest importance, so that the case may be dealt with while the growth is strictly localised. That will bring me to the third point upon which I wish to speak—namely, the treatment. The great point about the treatment is this: that I advise you when you meet with the disease in an advanced stage, as is so frequently done, to divide the operation into two stages rather than to treat the whole affair at once. Those two stages are, first of all to do a colotomy, so as to relieve the acute symptoms, and then when the patient is in the normal condition as regards physical strength to do an anastomosis.

First of all we will say a word or two upon the comparative benignity of the columnar-celled carcinoma. The structure of it I need say nothing about because you know that perfectly well. Its situation is either in the rectum or in the sigmoid flexure or in some part of the colon as a rule, the commonest being perhaps the rectum, next the sigmoid, after that the ascending colon, then the splenic flexure, the transverse or hepatic flexure, and then the descending colon or cæcum I have seen these cases where the whole lumen of the gut has become entirely obliterated. When one has come to turn it out of the abdomen one has found a little growth, perfectly moveable, completely localised in the wall of the gut, and when one has come to look for the lymphatic glands and the mesentery one has found them quite healthy. That is an experience which I have had over and over again, especially in former times when the condition was not so often diagnosed during life and when no surgical methods were taken to relieve the patient. On many occasions I have met with cases of this sort where there has been columnar-celled carcinoma of the sigmoid or of some portion of the colon, but it has been entirely localised; there have been no lymphatic enlargement of the mesentery and no obvious lymphatic glands. Then I can appeal to cases which I have treated. For instance, this specimen is a cæcum which I removed some years ago at the Bromley Cottage Hospital. You will see that it is a very considerable mass. Still, some six months ago I asked about this patient and she was brought to the Bromley Hospital for inspection eight years after the operation. She is still in excellent health; there is a little bulging of the cicatrix but that is nothing. There is another case which some of you who have dressed for me will remember very well—that of an old lady who had one of these columnar celled carcinomata which I removed and united the intestine above and below. With regard to this case we managed to trace her and found her in excellent health with no recurrence whatever. Therefore I say, whether I appeal to the post-mortem room or to cases which I have operated upon, I think my first proposition is borne out—that the columnar-celled carcinoma when confined to the intestines is at first a localised growth, that it may exist there for a very considerable time, that it may cause so much constriction that you can scarcely pass a stream of water through the stricture, but still there may be no general affection of the system.

---

[1] The lecture was illustrated by specimens.

The specimens from the cases I have mentioned are in the museum and afford abundant evidence of what I have said. I think you may take it on my authority that the columnar-celled carcinoma is at first a purely localised growth and if got away early enough there will be no recurrence at all. But if it is allowed to persist you get secondary glandular affections, as in the poor woman now in the wards. In this woman at the operation the colon was apparently free, but since she has been out of the hospital she has developed a large mass in the pelvis and you can see it very plainly, a huge mass blocking up the pelvis and making pressure upon the bowel and the bladder. So, although it is comparatively benign at first, if it is left there is the tendency which is noticed in all carcinomata for it to become disseminated. You will thus see that it is most important to make an early diagnosis.

Here is the specimen from the case of a woman who was sent to me from the west of England. She had a columnar-celled carcinoma of the cæcum. A curious circumstance is that just as I was making up my mind to give a clinical lecture on the subject I received a letter from her husband saying that she has had no trouble since and that she is in the best of health. The operation was done 12 months ago. She has no sign of constipation, her bowels are acting well, and she has put on flesh. That is a third case.

Now about the early diagnosis. First, the diagnosis of stricture of the colon. Given a well-marked case there is no great difficulty. The symptoms are these. The patient will tell you that he has had constipation for some years and perhaps 12 months ago he had what he called a bad attack of constipation, the bowels were confined for three or four days, or it might have been a week, and he felt a little sick, but not much; perhaps there was only retching but no actual vomiting. There will have been a good deal of pain and rumbling in the abdomen. Then perhaps he sent for a medical man and after having a number of enemata and castor-oil and purgatives a huge liquid motion was passed; some will say it was a pailful and then the patient has become apparently quite well again. Perhaps matters went on all right for three months and then at the end of that time a similar attack was experienced, only a little worse. Still, by repeating the medicine and treatment it was recovered from. Finally, the patient will probably come to hospital because of an attack which did not yield to the ordinary treatment which was successful previously. With such a history as that one should always think of a stricture of the colon. Then you will most likely find this: that the constipation gradually increased notwithstanding that the patient took his favourite pills and that the case had gone on to complete obstruction, perhaps even without flatus having been passed or only a little passed from time to time. The tongue is furred, there has been some retching but perhaps no actual vomiting, and the abdomen is distended considerably and most likely larger on the right side than on the left. At the same time the patient does not look so bad as if he had a stricture of the small intestine or some acute mischief there; indeed, in many cases he walks to the hospital With such symptoms as I have sketched you may be sure that there is stricture somewhere in the colon. Then, if the distension is more on the right side and there is some particular swelling over the cæcum that does not point to the cæcum so much as to the sigmoid, because when you get stricture of the sigmoid the bowel becomes distended. It is always the cæcum which becomes most distended and we know from post-mortem experience that when death occurs it is not as a rule immediately above the stricture that the bowel gives way but somewhere about the cæcum; ulcers form there and peritonitis ensues. Most practitioners would recognise a case where the disease was advanced like this, and if, on putting your patient under chloroform you feel a lump in the region of the cæcum and the patient is about 60 years of age or over and has been losing weight, you might with great certainty say that we are dealing here with carcinomatous stricture in the colon. Of course, that presumes you have examined the rectum and have found nothing there Those are the main symptoms.

What are the early symptoms which would lead to the diagnosis? Because when it has reached this stage you may have got a glandular affection with lymphatic involvement As far as I know the symptoms are these. Where I have cross-questioned the patients freely I have generally found that before these attacks of constipation came on the symptoms may be divided into the following four or five. First of all there are indefinite symptoms of abdominal disturbance, there will be uneasiness after food but not altogether referable to food. Sometimes the symptoms come on after food, sometimes before it. You question the patient and see if the symptoms are like those of carcinoma of the stomach—that is to say, the pain coming on four or five hours after food, or whether it comes on immediately after food like ulceration of the stomach. You find that that is not so. Then the patient probably says that he suffered from flatulency, and then there is pain referred to the heart from distension of the stomach. In addition to these indefinite symptoms there is nearly always a history of constipation, often with eructations, which are generally attributed by the patient to "indigestion." That is what I have found. Close questioning of these patients shows they have had the symptoms of indigestion continuing for some months or even years. Of course, when you get into family practice you will find many patients with these symptoms and of course they have not all got stricture. But I say that when these symptoms have existed for some time after the ordinary drugs have been tried and the patient has had change of air and scene, after he has been judiciously dieted, I say if they still continue you should be suspicious of stricture. Then, secondly, there are attacks of pain and spasm referred to the colon, with no reference to food. Those I have found to have very frequently occurred before definite symptoms have come on Thirdly, there are nearly always liquid stools. Still later the patient says: "I rarely have a solid motion," or "I only occasionally have a solid motion but very often liquid ones." Fourthly, there is a slowly progressive loss of weight; it is a symptom of great importance. Fifthly. there is a constant desire to defecate. With these indefinite symptoms of indigestion, loss of weight, and a tendency to liquid fæces, and with a history of constipation, one should always make a careful examination, especially if the symptoms have persisted notwithstanding drugs and dieting. You are first of all to look at the rectum. I was impressed with this only two years ago when I was coming home from my holiday. I was asked to see a patient who had symptoms of that sort. He had seen several physicians. Some had called his complaint gastritis, others said it was enteritis, but none of them examined his rectum. I passed my finger into the rectum and there found a columnar-celled carcinoma, high up, just within reach. Another case I remember very well in a medical friend who had these same symptoms and I said, "I am afraid you really have got stricture." He said, "No; nonsense; I have piles and a small fistula." He asked me to treat his piles. I said: "I do not think piles are at the bottom of this trouble " He saw an exceedingly well-known physician and he called it reflex spasm, the result of stricture. As a surgeon I am not acquainted with reflex spasm of the bowel above as the result of piles or of fistula; I am unfamiliar with it and I could not take such a diagnosis. Meanwhile, my poor friend went on getting worse and worse. One day when I saw him he said: "I am continually in the water-closet"—he was in a good consulting practice—and he had this most inconvenient constant desire to defecate. He would not let me do anything, but he got an attack of acute obstruction and another surgeon performed colotomy and two carcinomata were removed and the patient died afterwards. I am sure that if my poor friend had taken my advice two years earlier he might have been living now.

Those are the signs which I think should lead you to suspect carcinoma of the colon. I would digress at this point and say that if these signs which I have narrated are present you should examine the rectum and if you find nothing in the rectum put your patient under an anæsthetic and palpate the abdomen and then you may discover a tumour in some region. Failing that, what should you do? I advise you to do this: to have the patient weighed weekly, still persevere with your drugging and careful dieting, and then if the signs do not clear up make an exploratory incision; I am sure it is *justifiable*. When *symptoms such* as I have described do not clear up with the ordinary routine treatment, do not let the patient go until a definite tumour forms or acute obstruction supervenes, for it will then be too late to do much good.

That brings me to the third point—namely, treatment. What are my reasons for taking two bites at the cherry of treatment? *Why perform the operation in two stages?* Think for a moment of the condition the patient is in who has acute obstruction supervening upon a stricture of this character. *Some of you may ask, How* do you *account for the acute obstruction coming on?* You may account for it in several ways. Here is a stricture which has gone on steadily increasing despite purgatives and enemata, but a little fæces ooze through and perhaps you get some hard fæces through, and from some cause or other, such as massage, the portions of bowel get invaginated and the stricture may thus become blocked. And then from some of these causes the patient has got acute obstruction grafted on to the chronic. What is his condition? The bowel above is distended—let us take the local condition first—and below it is contracted. If you perform the operation then you have a huge bowel above to unite to a small bowel below, and that adds to the difficulty. What else have you got? The parts above have become inflamed, we will say, and are softened and therefore are not in a good condition for holding the stitches. And then look at the difficulty of the operation. There is this huge and *distended* bowel. *If any of you have* seen colotomy performed you will have noticed that as soon as the bowel is opened, by a little movement of the patient the fæces come out, and as soon as you have cleaned that little away more comes; and when you try to unite the bowel more fæces come out and there is danger of getting the peritoneum soiled. Therefore there are many local objections to the procedure. You have the whole of the small intestine above full of fæces and sometimes gallons of fæces will come out after you have done a colotomy and you have to get rid of this before you can make an efficient suture, and this danger of soiling the peritoneum is a very real one Then look at the general condition of the patient, how unfit he is for operation. Perhaps he has been constipated for a week or he may have been vomiting for two or three days; his tongue is furred, his breath foul; he is exhausted from lack of food, or, as is too often the case, he has been fed with nourishment injudiciously and the food has been vomited and his condition is as bad as it can be, for he is the subject of ptomaine poisoning, or, at any rate, absorption. His local conditions, then, are about as bad as they possibly can be for making an anastomosis.

Another objection is, supposing you do not feel the carcinoma when you open the abdomen you have to search for it and there again you know what a serious thing it is to search among overcharged intestines, for a scratch of the gut in such circumstances may injure the peritoneal surface and so allow the bacillus coli communis and other cocci which may exist in the fæces and which have perhaps already invaded the mucous and submucous coats to invade the peritoneum. So everything is against it. To my mind the best thing to do is, supposing you have made up your mind as well as you can that it is probably in the sigmoid flexure that the trouble is, to open the sigmoid, because it is a much better operation to open the sigmoid than to open the cæcum, for if you open the cæcum a quantity of liquid fæces comes away afterwards and the patient is not comfortable. One patient on whom I performed an operation on the cæcum some years back said: "I am like a walking water-closet; it is difficult *to keep out of the water-closet." Therefore it is much* better to open the sigmoid and it is much more common to have the growth in the sigmoid than in any other part of the colon. If you are in doubt, therefore, the first thing to do is an inguinal colotomy; then put in your fingers and draw a little piece of the sigmoid into the wound If it be distended it is quite clear that the stricture is below. If it is not distended the stricture is above. If with one finger put down you come at once upon a growth I have no he [illegible] out on to tl [illegible] You simply [illegible] that it shal [illegible] above. *It all bulges out as soon* as *you have it out* on the wall of the abdomen and then you put in a Paul's tube with a piece of indiarubber. Open the part and then send the patient back to bed and let it drain. If you are lucky you can do *that operation in a quarter of an hour and it cannot do the* patient any harm. You have now drawn the carcinoma on to the abdominal parietes, you have put in the Paul's tube, and you have relieved the patient of his constipation and sent him back to bed, and he gets straightway well. The fæces drain away and there will be a gallon or two. He recovers from his ptomaine absorption, the abdomen becomes flat, and then you can effectually deal with him. He is now in a very different condition for having an anastomosis done in comparison with what he was before when his bowel was overcharged with fæces.

So much for when you can feel the carcinoma. But if you cannot feel it what should you do if the sigmoid is distended? I think that the best plan then is to perform a colotomy. Simply draw out a piece of sigmoid and put in a Paul's tube and open it as before and allow the fæces to drain away. After that is finished and the patient's abdomen has become flat, as it will in ten days' time, you may search for the stricture. How would you search for it? Would you open the abdomen in the middle line and put your hand in and feel for it? Not at first. The first thing is, having got rid of the Paul's tube and having got further adhesions formed round the colotomy wound, to pass your finger into the lower end of the bowel, and the chances are that you will find it, as I did in the second case mentioned in this lecture. When the patient's abdomen became flat I passed my finger down the colotomy wound and four inches down I found the carcinoma. *She was rather an old woman and I did not do in her* case what I have done in others: I made a separate incision here and I brought the carcinoma on to the abdominal parietes The intestine above was emptied because it was drained by a colotomy wound and it had been washed out through her anus. I pulled the bowel out and I had healthy bowel above and below united by a Murphy's button and all went perfectly well. Then I had the colotomy wound to deal with. Why I left that wound open in her case was, as she was an old woman and moderately feeble, if anything went wrong with the button I should have had the fæces passing out and should not get soiling of the peritoneum. After I felt she had good union of the intestine, the carcinoma having been taken away, I closed the colotomy wound and let her pass her motions the right way.

If you find the sigmoid empty what should you do? I think in the text-books we are told to turn the patient over and to perform an operation on the opposite side. I would not do that at first; I should first of all search carefully with [illegible] there you may [illegible] flexure, say. I [illegible] Mr. Willett had a case of that sort, as his case came on immediately after one of mine. I came at once upon the sigmoid in mine; I found it distended, put my finger in and felt the growth, brought it out on to the abdominal parietes, and left it there for the time being. In Mr Willett's case the symptoms were very similar and he did the same thing, but he found the sigmoid collapsed and empty; he passed his fingers up and asked me to pass mine. We felt there a carcinoma in the splenic flexure and that was drawn out of the wound in the same way, left on the parietes, and a Paul's tube was put above the growth. If you cannot feel it the next best think is to turn the patient over and to perform a right inguinal colotomy, to place a Paul's tube in, and to let it drain from the right side. Again, when you have the abdomen flat, examine with your finger through the colotomy wound, passing it up the bowel and seeing if you can come upon the carcinoma in the hepatic flexure, and if you cannot make an incision in the middle line and pass your finger or your hand in and search the transverse colon.

As to the method of union I use a Murphy's button; others use sutures for the same thing. I think the advantage of Murphy's button is that by its aid you can perform the operation so quickly, and as most of these patients are elderly and their tissues not very resistant I think it is better to get the operation completed as quickly as possible rather than to run the risk of a long operation on the table. A Murphy's button, as you know, can be put in very quickly.

What would the operation be? Let us take a case of this sort, the first stage being when you have got the cancer out on to the abdominal parietes. Here is the intestine discharging fæces, here is a huge mass of carcinoma. Of *course*, you give purgatives and enemata so as to have this part of the bowel thoroughly empty. Then you take a piece of iodoform gauze and pass that well into the upper tube, so as to plug it up, and having done that make an incision round the wound, dissecting very carefully between the intestines, and if you are lucky you may sometimes succeed without opening the peritoneum. Sometimes the visceral peritoneum has become adherent to the parietal peritoneum; you will only avoid wounding that where the growth is a small one. If you cannot do that you cut the edge of the peritoneum and pull the bowel well out, cutting quite clear of the carcinoma, and then unite the two ends together by a Murphy's button or by the sutures, as you may prefer. Having done that drop it back into the peritoneal cavity. If you have not discovered the growth then the operative procedure is somewhat similar. The best plan, if it is in an elderly patient, is to enlarge the colotomy wound and to draw the bowel out. Or if you have a difficulty as to how the patient will stand operation, make a separate incision, having the colotomy wound sealed with collodion gauze; cut out the carcinoma and unite the divided bowel by a button.

In cutting out the carcinoma there are certain things to do. How are you going to deal with it? If you make your incision over the intestines you can either take out a wedge-shaped piece from the mesentery which I do not altogether advise, or you may cut along the course of the bowel, tie off the vessels at each spot where they are cut and then bring the gut together and put a few sutures in the fold, for it is thrown into folds like a fan. What is the objection to cutting out a wedge-shaped piece? You might be unlucky enough to cut the nutrient vessels and then you interfere with both parts of the bowel. If you cut along the edge of the mesentery you can only destroy the small vessels which come up to this part of the colon. It is safer not to cut out a wedge-shaped piece.

Those are the points that I wanted to bring out in connexion with this subject and I will recapitulate them. First of all columnar-celled carcinomata are one of the most benign forms of cancer that exist. At first the carcinoma is localised to the bowel; it has not affected the lymphatics and if you cut it away early enough you may cure your patient or you may give him eight, four, or three years of relief. For all I know some of the cases I have mentioned to you may be cured for there has been no recurrence in one of the cases for eight years and you cannot have anything very much better than that. I really wish you to think of these symptoms which I have mentioned to you when you meet with a patient. Go thoroughly into the case and please do not put it down to indigestion but watch and weigh the patient from week to week and if he does not get better examine the rectum and the abdomen under an anæsthetic. If the patient does not improve make an exploratory incision, for such an incision will do no harm and may do a great deal of good by discovering the carcinoma at an early stage. And if you are driven to perform an operation in a patient in whom undoubted symptoms have come on, if you take my advice you will do it in two stages for the reasons I have given; it is much safer than doing the whole operation at one time.

ABSTRACT OF

The Harben Lectures.

Delivered before the Royal Institute of Public Health, London, in the Lecture Theatre of King's College, in October, 1903,

BY FERDINAND HUEPPE, M.D.,

PROFESSOR OF HYGIENE IN THE GERMAN UNIVERSITY OF PRAGUE.

LECTURE I.

Delivered on Oct. 8th.

GENERAL VIEWS ON THE ETIOLOGY OF INFECTIOUS DISEASES.

THE lecturer began by referring to the fact that both scientific researches and practical measures in modern hygiene were influenced and determined by their knowledge or conceptions of the mode of origin of diseases. A want of agreement existed as to what constituted the cause. On the one hand, as in tuberculosis and leprosy, the individual constitution played a considerable part; on the other hand, external causes might operate chiefly in such diseases as cholera and plague. The study of the latter class of diseases led to an exaggeration of the importance of external causes alone as against the constitutional causes, for in both groups of disease specific disease-producing germs were found. The work of Pasteur and Koch led many to hold the germ as the sole cause, in opposition to the teaching of Goodsir and Virchow, who claimed that the diseased cell constituted the disease entity. A third view was that associated with the names of Simon, Parkes, and others in England, and Pettenkofer in Germany, this view being that other external conditions, defined as "predisposition of place and time," played a very considerable part, this being notably the case in typhoid fever. He (Professor Hueppe) had tried since 1888 to lead others to recognise the importance of all the three views above described, the one or the other of which had been held too exclusively. They all knew of persons who escaped a disease to which they might be exposed whilst others were attacked. This common observation led to the conception of "predisposition" in disease, a factor which had been denied by Koch and others. There was now a greater inclination to accept "predisposition"—it was a fact which must be reckoned with to-day. He (the lecturer) did not consider predisposition as something negative as opposed to the (positive) immunity which might be acquired after an attack of a disease. He considered predisposition as positive as immunity to which it was correlated. Chemical methods had not led them to an understanding of the constitution of the protoplasmic molecule, they had had to resort to biological methods "through impulses which correspond to the atomic groups of the protoplasm." He referred to such an impulse as a stimulus, and this stimulus could only be exerted if, let us say, the germ from which it emanated possessed side-groups such as were found in enzymes. He regarded this as the meaning of the specificity of disease-producing bacteria acting as stimuli. In normal physiological assimilatory stimuli they had, so to speak, to deal with a good key, whilst pathogenic bacteria might be compared to a false key fitting into, and possibly destroying, the lock which represented, figuratively speaking, the cell protoplasm of the animal body. This conception also applied to the processes of immunisation. Immunisation proved the existence of predisposition, increasing as it did the faculties which pre-exist as predisposition. They knew in the case of man that predisposition might alter according to age and that it might be affected by such external conditions as cold, heat, by hunger, alcoholism, &c., which might render an individual susceptible who might otherwise have resisted the inroads of a disease. Other diseases might also lower resistance. He (Professor Hueppe) believed that the descendants of mixed races might show an altered predisposition, citing in support of his opinion the observations made in Italy by Kruse with regard to the distribution of cancer; in southern Italy they had a relatively pure Ligurian population, in northern Italy a mixed population of Germans, Ligurians, and Turanians, with cancer prevailing in the north. The opinion that disease germs were the only cause, the "specific entity" of the disease, was a dogma which could not be accepted for the reason that they might at times be harboured by healthy individuals without producing disease, as had been proved for the germs of diphtheria, pneumonia, tuberculosis, and cholera. These germs might live outside the body, as saprophytes, and were consequently not compelled to lead a parasitic life. What was more, their disease-producing power might vary and they did not affect different animals alike. Different germs might produce similar effects. Different individuals of the same species behaved differently to infection. These facts did not permit of their recognising either the disease germ or the diseased body cells as an entity in the process. The cellular pathologist made a mistake in only considering the structure of the animal mechanism, the bacteriologist also fell into error by concluding that his laboratory infection experiments with pure cultures were equivalent to what took place in naturally acquired infection. In proof of the last statement they had only to cite the instance of the guinea-pig which was highly susceptible to laboratory infection with tubercle bacilli but was practically never infected naturally.

In diseases which were conveyed by air, water, and food they might in certain instances succeed in avoiding infection by these means, but there remained the "genius epidemicus" of Sydenham, that was the fact that certain infectious diseases did vary in different epidemics with regard to extent and intensity, a variation which was attributable to the influence of environment as a stimulus in the Darwinian sense. They knew that the pathogenic power of a germ might become modified so that it behaved like a harmless saprophyte when introduced into the body. He (Professor Hueppe) accepted this as evidence in favour of the origin of *all infectious diseases being phylogenetically traceable to* putrefactive processes. According to the degree of adaptation to parasitism he distinguished germs which were facultative parasites, facultative saprophytes, and obligatory parasites. Disease he regarded as a function of three changeable factors—viz., predisposition, stimulus, and condition, each of which might vary from 0 to infinity. He represented this by an equation such as *follows, in which I stood for illness,* P for predisposition, S for stimulus, and C for condition, thus I = f (P, S, C). If the factor C was constant or negligible it might be dropped from the formula. Each of the factors might be composed in turn of factors; thus P could be due to p (inherited predisposition) and p' (acquired predisposition) in which case they had. I = f (p + p', S, C). The factors could be examined separately; thus the relation between P and the quantity of pathogenic germs introduced was studied by Ammon and a curve was plotted according to Gauss. The different factors concerned in disease would have to be studied by many different means. The object of hygiene would be to decrease their *predisposition and to increase their resisting power against* disease. Professor Hueppe concluded with the words: "Practice alone brings us into a groove from which there is no outlet, but practice combined with scientific research guarantees progress in public health."

LECTURE II.

Delivered on Oct. 12th.

Hygiene and Serum Researches.

In the previous lecture it was stated that specific pathogenic germs only represented a specific stimulus, other factors, notably predisposition, being concerned in disease. In the earlier work on disease Metchnikoff's phagocyte theory was hailed by pathologists, but viewed in the light of this theory as then expressed predisposition constituted something entirely negative, an inability of the phagocytes to cope with the invading germs. Metchnikoff referred an important function to the cells, whereas others inclined to the so-called humoral theory according to which the presence of bactericidal substances in the body fluids constituted the means of defence. The divergent views were united by subsequent researches which showed that bactericidal substances were produced in cells. It was shown that cell-free blood could destroy germs, that this power could be increased in specific immunisation. There were two groups *of diseases in which*, on the one hand, as *in cholera* and typhoid fever, the acquisition of immunity was shown by the presence in the blood of specific bactericidal substances; on the other hand, as in tetanus and diphtheria, the growth of immunity led to the formation of substances in the blood which were capable of destroying the poisons which were given off by the specific germs. A condition might, however, exist in acquired or inherited immunity where both bactericidal and antitoxic substances appeared in the blood. By separating the germ from its toxin they were able to obtain either antimicrobic or antitoxic substances in the blood during the process of immunisation. Antitoxins, as they knew, were used therapeutically, they cured but they did not immunise; in fact, they cured because they did not immunise. Habituation or tolerance to a poison did not depend on antitoxins, according to the lecturer, for antitoxin-formation was only accessory to toxin-immunity. Toxin-immunity depended upon toxin serving as a stimulus to susceptible cell protoplasm. The lecturer agreed with the main conception of Ehrlich's theory regarding the mode of interaction of toxin and cell protoplasm through haptophors and receptors, &c. The following passages contain his main views. He considered natural resistance, artificial habituation, and susceptibility to toxins to be correlated and that a similar correlation existed in immunity due to bactericidal substances. Professor Hueppe explained the familiar views of Ehrlich, Bordet, Pfeiffer, and others with regard to the *mode of action of bactericidal sera*. Already in 1895 he wrote: "The property of specificity may not unreasonably be conceived of as a quantitative variation and as dependent upon the bringing into action of normal powers by appropriate stimuli." This conception had since been accepted by Ehrlich and others. Immunisation was only the augmentation of faculties which were performed as disposition. Predisposition was something positive but it did not suffice to protect the body against infection.

LECTURE III.

Delivered on Oct. 13th.

Tuberculosis.

Whereas tuberculosis was formerly considered to be a constitutional disease by the majority of physicians the belief that it was an infectious disease grew and culminated in the discovery of the tubercle bacillus by Koch in 1881. Sanatorium treatment, begun by Brehmer, demonstrated the curability of the disease by raising the resistance of the individual affected Consequently they had the specific bacillus and predisposition to deal with as factors in the causation of the disease. The erroneous view of some bacteriologists who ignored predisposition was based on laboratory experiments where large numbers of bacilli were introduced into the body, this in a manner which never took place in natural infection. That tuberculosis was frequently cured was shown by the records of necropsies. Virulent bacilli *had been found in the air passages of healthy persons* who had associated with the tuberculous. Tuberculosis was so general that every individual had an opportunity of becoming infected; the majority, however, remained healthy. Formerly the tubercle bacillus was regarded as an obligatory parasite, a view which had had to be modified since its successful cultivation upon glycerinated media, especially at temperatures beneath that of the body. The bacillus might become attentuated in cultures and it showed variations in virulence in the animal body. *Professor Hueppe opposed the famous* dictum of Koch with regard to the intercommunicability of bovine and human tuberculosis, on the grounds that different races of cattle had been found to possess different predispositions to infection and that numerous investigators had succeeded in infecting cattle with bacilli of human origin. Behring found human tubercle bacilli which did not at *first infect cattle to be capable of doing so* after passage through the goat. Anthropoid apes had been infected with human and bovine bacilli, as had also human beings. Cattle had been rendered immune to bovine tuberculosis by treatment with bacilli of human origin. Human and bovine bacilli must therefore be regarded as but varieties of one species of micro-organism. These varieties might show morphological differences and necessarily, in consequence of adaptation, they would show differences of virulence when obtained from the bodies of different species of animals. Similar observations had been made with regard to other bacteria—viz., the bacteria of septicæmia hæmorrhagica and the streptococci. Bacilli of avian *origin* had also been modified and they were forced to conclude that these also were but varieties of the mammalian bacillus. Opinion with regard to the mode of infection had undergone a change since Koch claimed that pulmonary tuberculosis indicated that the port of entry for the bacillus was through the respiratory passages. Several observers, including Professor Hueppe, had shown that pulmonary infection might also follow when the bacilli entered the lungs through the lymphatic and blood circulation, and Grawitz had pointed out the possibility of infection through the tonsils. Experiments made in Professor Hueppe's laboratory showed that if rabbits were fed with tuberculous material some developed intestinal and others pulmonary tuberculosis. Baumgarten produced pulmonary tuberculosis in rabbits through incoulations into the bladder and bacilli might be carried to the bronchial glands and lungs *from the submaxillary glands*. A special susceptibility of certain organs appeared to determine which organs should be affected. This was an entirely different view from that originally advanced by Koch. According to Professor Hueppe the *locus minoris resistentiæ* was to be found in the lungs in the adult and in the intestine in childhood. That a specific inherited predisposition existed was indicated by the fact that in certain families the children became tuberculous in succession on attaining a certain age. *In some cases the parts attacked* were often the same in the different members of a family. The fight against the bacilli alone would not suffice as a practical measure of prevention; they must also resort to hygienic measures which would increase the powers of resistance against infection. It was too early to form a judgment regarding the value of immunisation experiments against tuberculosis such as had been conducted by Macfadyen and von

LARGE BILE CYST OF THE LIVER; JAUNDICE WITHOUT CHOLELITHIASIS; INCISION AND DRAINAGE; RECOVERY.[1]

BY ALBAN H. G. DORAN, F.R.C.S. ENG.,
SURGEON TO THE SAMARITAN FREE HOSPITAL.

DR HALE WHITE considers that cysts of the liver not hydatid are very uncommon, seldom give rise to any symptoms during life, and are obscure in their mode of origin. Langenbuch, Waring, and Rolleston seem to be of the same opinion. On that account I think that the present case, where operative interference was necessary, is worth recording.

The patient was a married woman, aged 42 years, who was admitted into the Samaritan Free Hospital under my care on March 4th, 1903, suffering from deep jaundice and great enlargement of the liver. She had never been strong but had not suffered from any malady more severe than two attacks of influenza, the last being in December, 1902, when the jaundice was already marked. She had been pregnant seven times, bearing five children to term. Six years before admission she aborted at the second month through a shock caused by seeing a man carried to hospital after a street accident. No jaundice was observed as the result of the shock. The second abortion also took place at the second month. It occurred three years before admission and its cause must be dwelt upon. The patient slipped in her backyard and fell forwards, striking the right hypochondrium against the edge of a washing tub. A few hours later she aborted. She did not feel much pain in the hypochondrium after the smarting caused by the blow had subsided and certainly was not jaundiced. The last normal pregnancy ended by spontaneous delivery in April, 1901, and from that date the patient's health began to deteriorate. About four months before admission she noticed that her face began to grow yellow. Ten days before admission she suffered for the first time from a very violent attack of pain in the upper part of the abdomen, lasting for a few minutes. Several other such attacks followed and she felt gnawing pains across the epigastrium. She was troubled with diarrhœa, passing abundant semi solid white stools.

When I first examined the patient she appeared to be a somewhat emaciated woman, deeply jaundiced, the conjunctivæ being of a bright yellow colour. Itching was severe and kept her awake. She was naturally cheerful and quite free at the time from any depression, a point of interest in relation to an episode during convalescence. The abdomen was considerably distended and to the right of the umbilicus there was a large fluctuating swelling which I noted at the time as in the situation of the gall-bladder; it reached to a little below the umbilical level and was very prominent, bulging under the skin. Hepatic dulness reached to the fourth rib in the line of the nipple The edge of the left lobe of the liver reached the umbilical level; it was thin, easily grasped, but very tender. The pelvic viscera seemed to be healthy; the catamenia had become scanty during the present illness but remained regular. The pulse was 84, small, hard, and regular; there was no œdema of the legs or of any other part, nor were there hæmorrhoids. The heart and the lungs were healthy. The temperature was 100° F in the mouth on the night of admission but fell to normal after rest in bed. The appetite was fair. The urine was always turbid and deep orange-brown in colour, the specific gravity being 1022 to 1024; it cleared on boiling, becoming light olive green; on adding nitric acid, or boiling after the addition of the acid, a precipitate, deep purple in colour, appeared. There was no sugar.

I operated on March 10th with the assistance of Mr. A. C. Butler-Smythe; Major P. Carr White, I.M.S., worked the aspirator and Mr F. W. Collingwood administered ether and chloroform. I made an incision along the outer border of the right rectus over the prominent fluctuating swelling. There was no oozing; one vessel required ligature. A large cyst appeared with semi-opaque greenish-brown walls. I took it at first to be the gall-bladder. A pad was slipped into the kidney pouch and another below the liver; then the aspirator was used and two pints eight ounces of pure deep green bile were removed. When the cyst collapsed I found the gall-bladder perfectly healthy behind and below it The cystic, hepatic, and common ducts were plainly visible; they were quite normal and empty. The pancreas was soft and supple and there were no omental or intestinal adhesions. The right lobe of the liver was enlarged, the surface was not irregular but opaque from perihepatitis; the left lobe was of a uniform rich orange brown colour, with the capsule quite free from opacity. No calculi or any more cysts could be felt in the liver. The great cystic cavity occupied the lobulus quadratus and apparently the whole of the left half of the right lobe to the diaphragm and the back of the abdominal cavity. The gall-bladder was about three inches long, thin, and flaccid; it contained a little fluid, presumably clear, and was very moveable; the cyst had pushed it away from its groove. Its walls were healthy and no calculi could be felt. The right kidney was healthy and mobile. I inserted a quarter-inch red rubber tube into the cyst and sewed the edges of the opening, which I made around the aspiration puncture, to the peritoneum at the upper angle of the wound. The rest of the peritoneum was united with a continuous No. 1 silk suture and the sheath of the rectus (I had not divided the lateral muscles) in the same manner; the wound in the integuments was closed with interrupted silkworm gut. The patient slept well a few hours after being put to bed; I withdrew on the same evening 16 ounces of pure green bile. Dr. Cuthbert H. J. Lockyer examined the bile removed at the operation; it contained no trace of clot or hydatid elements.

The temperature during convalescence never exceeded 100°; the pulse was 96 for several days. The itching disappeared within 24 hours. The area of hepatic dulness was found to be reduced to its normal limits; the left lobe became less and less tender to touch. During the first week the dressings were saturated with green bile and about a pint of bile was removed through the tube daily by the aid of a syringe. The rubber tube was gradually shortened but was not entirely removed until the seventeenth day. Early in the third week the patient was depressed, as is often the case in jaundice, but the complexion continued to clear. On April 3rd the nurse informed me that the motions passed in the morning were coloured. On the next day I examined them; they were of a medium brown colour. The patient was once more cheerful; the conjunctivæ had become pearly white Henceforward till April 17th, when the patient left the hospital, 38 days after the operation, the motions remained dark and the discharge from the fistulous track left after removal of the tube diminished. An ounce or two of purulent bile were removed every morning through the track; the cyst was occasionally washed out with chinosol. The patient came to the hospital occasionally after her dismissal to have the wound dressed, but the cavity was syringed out daily at home with Condy's fluid On Oct. 19th, when I last saw her, she was in very good health though pus was still discharged from the fistula.

Pathology —Rolleston, Waring, Hale White, and others who have written on simple non-hydatid cysts of the liver admit that they are exceptional, obscure in their mode of origin, and rarely give rise to any symptoms during life They further imply that such cysts are usually small. Kilvington states that very large cysts of this class are nearly always single. None of these writers finds that simple cysts contain bile Specimens in the museums of hospitals in London do not throw much light on the present case. On inquiry I have been informed by the curators and pathologists of these institutions that no example of a large cyst which contained bile is to be found in these museums. Of the specimens in the museum of the Royal College of Surgeons of England the only one in any way akin to my case is No. 2757B which I find is figured in Waring's treatise (Fig. 22) That author observes that it is of about the size of a walnut and attached to the anterior surface of the liver immediately above, and to the right of, the gall-bladder. It seemed to me to be connected with the gall-bladder and only separated from its cavity by a thin septum; it may therefore represent a congenital malformation of the gall-bladder itself; it held an albuminous fluid. The cyst in my case contained pure bile and was quite unconnected with the gall-bladder.

Reported cases of la [illegible] In several instances cysts of the liv[illegible]ting from the surface of that organ [illegible] oved more or less completely by operation. Langenbuch refers to cases reported by Müller of Aix-la-Chapelle, Berg, and Hueter; other cases have been reported by Kaltenbach and Ward Cousins. Five cases where a unilocular, not hydatid, cyst lay inside the liver have been reported by Kilvington (operation by Frederick Bird of Melbourne), Bayer of Prague, Winckler, North, and Mayo Robson. In the cases reported by Bird, Bayer, and Winckler there was neither jaundice nor cholelithiasis; in Winckler's alone was there any trace of bile in the contents of the cysts. In North and Mayo Robson's cases there were jaundice and obstruction from calculi in the common duct, very definite in North's case. The contents seemed to consist more or less of bile in North's case, whilst in Mayo Robson's case bile flowed from the cyst after it was opened. In my own case there was marked jaundice but no trace of cholelithiasis; the cyst contained pure green bile.

---

[1] A paper read at a meeting of the Royal Medical and Chirurgical Society on Oct. 27th, 1903

Quite recently Miller of Washington opened and drained a cyst containing five pints of bile in a girl under three years of age; the abdomen was enlarged at birth. The motions were pale and jaundice was absent; after the operation the motions became coloured. Miller considers that the tumour was a congenital dilatation of the gall-bladder and bile ducts, but the tumour occupied part of the liver, the round and suspensory ligaments being attached to its upper surface. Thus Miller's case may be of the same character as my own. I shall refer to it presently in reference to heredity.

Cavities in a liver containing gall-stones.—In the cyst which I opened no gall-stones were found nor did any come away through the fistula. In Case 22 in Mayo Robson's text-book the gall-bladder was opened and a number of gall-stones were removed; many more calculi were then found lying mixed with semi-purulent fluid in a cavity in the liver substance itself, "having evidently ulcerated through from the gall-bladder." But in the present case the gall-bladder was free from calculi, disease of its coats, or adhesions to the liver. Knowsley Thornton once removed a number of calculi from a cavity in the liver but I cannot ascertain whether the gall-bladder was in any way involved.

Having made some mention of other cases of bile cyst in the liver I will now dwell on certain more or less essential features in my own case.

The cause: injury or pregnancy?—The history of a blow on the right hypochondrium nearly three years before the jaundice set in is, to say the least, highly suggestive. It was severe and abortion followed in a few hours. This blow might have caused the rupture of a duct inside the liver followed by very slow extravasation of bile into bruised liver substance around it. A cystic cavity could thus be formed and ultimately all the bile secreted in the liver might be poured into the cyst. The pressure of the cyst in some way prevented the passage of the bile into the hepatic ducts; possibly, however, a small calculus blocked each of the main ducts which unite in the transverse fissure to form the hepatic duct. The evidence gained during the operation almost proved that the original seat of disease was entirely inside the liver. The cyst occupied a great part of that organ; [illegible] the right lobe was thick and opa[illegible] structure and over the left lob[illegible]ansparent. There was absolutely no trace of inflammatory changes around the hepatic, cystic, and common ducts, the gall-bladder, and the lesser omentum.

Against the theory of injury in my case it may be urged that blows on the right hypochondrium are common and seldom appear to cause damage to the liver; whilst when they do that damage is generally rupture involving the fibrous and serous coats. There is, of course, no absolute proof that the liver was damaged when the patient fell against the washing tub. I must dwell on the fact that pregnancy occurred and went on to term between the date of the accident and the appearance of the jaundice.

Congenital disease and heredity.—The pathologist may suggest that there was some congenital malformation or disease in the intrahepatic ducts, the results of which did not for some reason develop until adult life. There was no way of getting at any proof of such a condition in my case. The patient's children and near relatives seem never to have [illegible] symptoms of cholelithiasis. [illegible] patient was 50 years of age [illegible] the age of three weeks, her [illegible]ce, when a month old, had severe epistaxis (a complication from which the jaundiced mother had always been free), and died in the fifteenth week "with a mottled black and yellow skin." In a case reported by me of very chronic jaundice which dated from early girlhood the patient's eldest child, aged 11 years, had suffered from a severe attack with no symptoms of gall-stones. The patient had four or five attacks, all unaccompanied by pain, before she was 18 years old; then for 15 years there were no hepatic symptoms; at length cholelithiasis set in. In Miller's case the cyst existed at birth and was drained before the patient was three years old. It is easy to conceive that a congenital cyst of this kind might lie latent until adult life. These remarkable clinical facts suggest that overlooked heredity was possible in the present case, whilst local pre-natal or infantile disease with unusually tardy results was quite probable.

The contents of the cyst.—At the operation the cyst contained over three pints of pure olive-green bile, two and a half pi[illegible] later. [illegible] normal [illegible] abov[illegible] cavity discl[illegible] clear and [illegible]mmon duct.

Jaundice.—This symptom was marked in my case, but why it appeared suddenly four months before operation I cannot explain. It began to subside when the bile flowed freely out of the drainage track after the operation, but the bile did not colour the fæces until the fourth week. Thus some obstruction must have existed till that date, although the pressure of three pints of bile had been removed at the operation. The cyst probably pressed on the ducts or set up catarrh in them, as has been observed when jaundice is associated with hydatid cysts (Waring). Perhaps catarrh existed in my case and did not subside until the fourth week; but the three ducts looked very healthy at the operation, so that it must have been the radicles of the hepatic duct that continued to be obstructed for a while by catarrh or some other cause. *The experiences of Bayer and Winckler,* as well as the familiar instance of hydatid disease, show *that large intrahepatic cysts are not necessarily associated* with jaundice.

Hæmorrhage into the cyst.—No trace of blood could be detected in the bile removed during the operation and little, if any, in the bile which drained away from the wound afterwards—in short, there was no hæmorrhage into the cyst. It is evident, however, that a patient who walks about with [illegible] pints of fluid is liable to that [illegible] Kilvington's case.)

[illegible] disease.—The total absence of hydatid membranes in this large cyst and the fact that the pure green bile which it contained was free from any trace of microscopical elements of hydatid cysts make it highly improbable that the cyst was a product of hydatid disease. Even supposing we assume that the cyst was hydatid and that an intrahepatic duct burst into it how could we make out that the bile or some other agent cleared away all traces of acephalocysts, hooklets, &c.?

Menstruation.—The catamenia had been regular during the existence of the jaundice but more scanty than before the illness. They appeared on the second day after the operation; the show of blood was distinct but slight. Cocking's case shows that a woman may menstruate regularly and bear *children although subject to jaundice from infancy. Jaundice* clearly does not necessarily cause menorrhagia, nor does amenorrhœa seem to be the rule; when present it is most likely the result of ill-health or anæmia.

Treatment.—The drainage of the cyst was clearly indicated nor did any further procedure appear to be called *for when I operated. The result was most satisfactory.* By the fourth week, when bile began to pass into the bowel, the chances that a second operation to establish a communication between the cyst and the bowel would be necessary became remote. It is not remarkable that suppuration has occurred in the track which is not likely to become obliterated for some time as the hepatic tissue cannot readily close in around a cavity so capacious. In Bayer's case an abscess developed a few months after the operation; probably the drainage track was allowed to close too soon. Infection from sutures is difficult to avoid when a big liver cyst is drained.

We must agree with Kilvington that the curette should never be used; there is usually no epithelium lining big [illegible] cysts that could secrete so as to fill the cyst again. That writer recommends that a simple cyst should be dropped back when all the fluid has been allowed to escape, but he adds that when calcareous plates are present or when there is any bile in the fluid drainage is necessary. Of course, dropping back the cyst, or rather the liver with the big cystic cavity inside it, would have been out of the question in the present case.

In conclusion, I think that the total absence of any symptoms of shock after this operation is instructive. The common opinion that an operation on the upper part of the abdominal cavity necessarily involves shock is quite untrue. The alarming symptoms sometimes observed seem distinctly due to prolonged handling of the pancreas, the duodenum, the great vessels, and the nerve plexuses. In the days when incisions were made very short the operator's fingers, working in the dark, must often have bruised these important structures. Now that the parts are freely exposed to the operator's eyes much less handling is needed. In this case I could see everything and the parts involved in chronic cholelithiasis were all free from disease. The liver itself bears handling very well.

ON THE GREAT IMPORTANCE FROM THE POINT OF VIEW OF MEDICAL SCIENCE OF THE PROOF THAT BACTERIA AND THEIR ALLIES ARE CAPABLE OF ARISING DE NOVO.

BY H. CHARLTON BASTIAN, M.A., M.D. LOND., F.R.S.,

EMERITUS PROFESSOR OF THE PRINCIPLES AND PRACTICE OF MEDICINE IN UNIVERSITY COLLEGE, LONDON, AND CONSULTING PHYSICIAN TO UNIVERSITY COLLEGE HOSPITAL AND THE NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC.

THE intimate relations that have been proved to exist between micro-organisms and so many of the contagious or communicable diseases, and the discovery that in many cases the organisms in question act as the veritable contagia by means of which such diseases are spread from person to person, have exercised such an enormous influence over the minds of medical men that they have led to the almost universal establishment of ultra-contagionist views in regard to all these diseases. Just, it is thought, as organisms are propagated only and do not arise *de novo*, so the reigning doctrine in medicine has been for some time, and still is, that contagious diseases are propagated only and never arise *de novo*. The breaking down of the prejudice in regard to organisms by showing that they can originate independently of pre-existing micro-organisms of like kind would of necessity exert a powerful influence over medical doctrines and would pave the way for the admission that contagious diseases may also arise *de novo* instead of being only disseminated by contagion. Short of a proof of this kind there seems less chance of any such widening of doctrine being brought about.

To show the kind of feeling that exists I may recall the fact that one of the most distinguished physicians in this country not very long since said[1]: "If I can trace contagion in a very large number of the so-called specific diseases I consider it more reasonable to assume contagion in the minority than look about for another cause." And he went on to say that as many of these diseases are associated with the growth and multiplication of "living specific organisms" a belief in the *de novo* origin of these contagious diseases would "imply also a belief in spontaneous generation." This latter notion is undoubtedly very common and has been one of the principal causes that has stood in the way of a belief in the possibility of the *de novo* origin of a contagious disease. On this account, therefore, the proof of the heterogenetic origin of bacteria becomes a matter of very great importance for medical science. Still, the conclusion above drawn, notwithstanding its prevalence and great influence, does not of necessity follow, as I shall hope to show.

We all know that common bacilli and micrococci are constantly making their entry into the body through the intestinal and the respiratory mucous membranes and thence are gaining access to the lymphatic system. So that for the origin of this or that specific disease it may not be at all necessary that a *de novo* origin of micro-organisms should take place. Under the influence of unhealthy local or general conditions the common micro-organisms thus entering into the body may possibly be made to take on new properties and be, in fact, converted into one or other of the so-called "specific" or "pathogenic" micro-organisms. It is needless for me to cite in support of this latter possibility the vast array of facts now known concerning the variations and interchangeability of form that may be brought about in these micro-organisms by changes in the media and conditions to which they are subjected, and the still more important variations in function and in the chemical processes associated with their growth and multiplication that may be similarly induced. This is so notoriously the case that many writers, such as Billroth, Nägeli, Warming, Cienkowski, Ray Lankester, Zopf, and others have regarded these micro-organisms as mere developmental phases or varieties, modified by external conditions, of one and the same or but a very few distinct species. Many facts of importance in this relation in connexion with pathogenic bacteria and their possible derivation from non-pathogenic forms are matters of common knowledge.

There is one case, however, so pertinent to the present inquiry and of such great importance in itself that some details will prove most useful. I allude to our present knowledge concerning certain experimentally produced diseases in lower animals included under the name septicæmia. Two of these forms of septicæmia have been investigated experimentally with the greatest care.[2] One of them, known as "Davaine's septicæmia," may be originated in a previously healthy animal by injecting two or three drops of putrid blood (bullock's or that of any other animal) into the subcutaneous tissue of a rabbit. The animal dies in from 23 to 25 hours, bacilli in myriads and of a distinctive kind existing, even during life, in its blood. This constitutes the origin of a disease which proves to be contagious, and so much so that it can be propagated from animal to animal by even the millionth part of a drop of blood and thus on indefinitely. The other form is known as "Pasteur's septicæmia" and it is produced at will in this fashion. Let two or three drops of putrid bullock's blood from the same stock be this time injected into the peritoneal cavity of a rabbit rather than into its subcutaneous tissue and now a different form of the disease is established, though one which is also contagious and equally constant in its characters. In this case the animal does not die so rapidly, and while bacilli swarm in the fluids of the peritoneal cavity within 24 hours they are not to be found at the time of death in the blood though they appear there and throughout the body in the course of a very few hours after death. Another difference between these two varieties of septicæmia is that though the latter form of the disease is also contagious and capable of being propagated indefinitely by the inoculation of a *minute quantity of the peritoneal fluid, yet this fluid* contains a contagium which is nothing like so virulent as that contained in the blood in "Davaine's septicæmia." Instead of one-millionth of a drop, which is adequate for contagion in this latter case, it is found that about a drop of the infecting peritoneal fluid is needed in the case of "Pasteur's septicæmia."

---

[1] Letter from Sir Samuel Wilks, Brit. Med. Jour., Dec. 23rd, 1893.

[2] See Report on Experimental Investigations on the Intimate Nature of the Contagium in certain Acute Infective Diseases, by G. F. Dowdeswell, Brit. Med. Jour., July 19th, 1884, pp. 101–8.

But now another and even more important point has to be mentioned. It is this. We are told that absolutely no difference can be detected between "Pasteur's septicæmia" and that which is initiated after the manner of Burdon Sanderson by injecting a small quantity of a germ-free chemical irritant into the peritoneal cavity or into the subcutaneous tissue of a rabbit. Difference in the site of introduction of the mere chemical irritant produces no difference in the disease. Its action in either situation is to set up a most virulent inflammation the fluids of which *speedily teem with bacilli*, and in every particular the malady so induced has been shown by other pathologists exactly to resemble "Pasteur's septicæmia." Burdon Sanderson's words concerning the actual *de novo* production at will of this contagious disease are as follows[3]: "If a few drops of a previously boiled and cooled dilute solution of ammonia are injected underneath the skin of a guinea-pig a diffuse inflammation is produced the exudation liquid of which is found after 24 hours to be charged with bacteria. ...... Other chemical agents will lead to the same results and *always under conditions which preclude the possibility of the introduction of any infecting matter from without*." Elsewhere[4] the same investigator refers to experiments which were made about the same time in order to throw light upon the cause of the appearance of bacteria in certain peritoneal exudations and to ascertain whether or not their presence was to be considered as "a mere result of the intensity of the peritonitis." He says: "To determine this experiments were made *during the following month (May, 1871) which consisted in inducing intense peritonitis* by the injection not of exudation liquids but of chemical irritants, particularly dilute ammonia and concentrated solution of iodine in hydriodic acid. As regards the ammonia, precautions were taken to guard against contamination by boiling and cooling the liquids as well as the implements to be used immediately before injection. In the case of the solution of iodine this was, of course, unnecessary. In every instance it was found that the exudation liquids, collected from 24 to 48 hours after injection, were charged with bacteria, whence it appeared probable [illegible] was dependent, not on [illegible] which the inflammation [illegible] *the inflammation itself*."

The organisms in the cases where germ-free chemical irritants have been employed have therefore come from the previously healthy body of the animal experimented upon—either by way of heterogenesis or by the waking up of previously "latent germs" of common micro-organisms, instead of being, as in the other experiments, modified descendants of the common putrefactive organisms contained in the bullock's blood. *But the point of importance is that* in either case, under the influence of local inflammatory processes of great intensity, such common organisms have been converted into specific or "pathogenic" micro-organisms, capable henceforth of preserving their specific characters and of "breeding true" in suitable media.

Dowdeswell, who has many times repeated these experiments for the production of both varieties of septicæmia, points out that the form named after Pasteur corresponds with what Koch has termed "malignant œdema" and that the bacillus which characterises it is an extremely common form often found in the outside world. Still, when the germ-free chemical irritants are used he declares his belief that infection from without is precluded and that the bacilli "originated from within the animal organism."[5] In regard to the production of the form named after Davaine it appears that putrid blood sometimes fails, especially in winter. Some particular stage of the putrefactive process seems necessary. Nothing more than this is proved, though Dowdeswell assumes, without adducing a vestige of proof, [illegible] *form of the disease in* [illegible] blood owing to "atmo- [illegible] nce tends to show that *it is one of the many forms developed at a certain stage* in the putrefying blood which is capable of infecting the system through the subcutaneous tissue but not when introduced into the peritoneal cavity. This bacillus of Davaine's septicæmia is, according to Dowdeswell, a so-called "specific organism" whose characters he has minutely described;[6] and it is not known to exist in the outside world apart from putrid blood in certain stages of change.

This production of two different forms of septicæmia by the inoculation of some of the same putrid material into different sites is a matter of the greatest importance. The putrid blood under the skin gives rise to one form of specific micro-organism and contagious disease, while two or three drops of the same putrid blood introduced into the peritoneal cavity of a similar animal give rise to swarms of a different organism and the development of another contagious affection. *The differences in the inflammatory processes in the* two situations are capable, that is, of transforming some common micro-organisms into two quite different specific bacilli, while the germ-free chemical irritants, with even more certainty, give rise to one and the same contagious affection whichever may be the site of their introduction. These are all facts the importance of which can scarcely be over estimated. They afford a sort of beacon light capable of illuminating the obscurity surrounding the origin of many other contagious diseases. A few examples will suffice to show the mode in which they may prove helpful in over coming difficulties which are commonly thought to stand in the way of a belief in the *de novo* origin of other of these contagious diseases.

In typhoid fever we have one of the commonest of contagious affections about the possibility of whose *de novo* origin the greatest difference of opinion has long existed, though of late the ultra-contagionist view has been decidedly gaining ground here as in other directions. *But there are, perhaps, some still who, while admitting contagion and the common spread of the disease through con*taminated water or milk or by other agencies, would be inclined to agree with Rodet and Roux that this disease may originate *de novo* and that the typhoid bacillus of Eberth is merely an altered and virulent form of the common bacillus of the colon.[7] The researches of these observers have tended to show that this latter bacillus, which commonly exists in the human intestine without harmful results, can become highly virulent and infective, under certain conditions, when introduced into water. Hence they conclude that not only typhoid dejections but simple fæcal pollution of water may produce typhoid fever in those who drink it. This is undoubtedly a very important point and one which hitherto has not been adequately taken into account by those who have attempted, as they thought, to trace the source of contagion in many cases of typhoid fever. Because there has been pollution of a water source by a man suffering from diarrhœa, and typhoid fever has been produced in persons drinking such water, it must not be assumed without proof that the man who polluted the water was suffering from typhoid fever. As bearing upon this view of Rodet and Roux it is interesting to note that typical enteric lesions in the small intestine have been artificially induced in lower animals by R. Row[8] of Bombay by intoxicating them with the products of the bacillus coli communis; and that the lesions thus produced have been even more marked than when similar animals have been intoxicated with the products of the more specialised bacillus of typhoid fever—though in the latter case death was produced with more pronounced general symptoms and also more rapidly than in the former case.

While one mode of origin of the disease may be brought about in the manner indicated by Rodet and Roux (that is, in a manner only too likely to be ascribed to a spread of the disease by water-borne contagia) it is well known that another quite different mode of origin of the disease was advocated by Murchison in his celebrated work on "Continued Fevers."[9] He believed that the toxic cause of typhoid fever might originate in pent-up decomposing fæcal matter and that in these cases the mode of entry of the poison into the system was through the air rather than by means of water taken into the alimentary canal.

Others, again, hold views closely related to this. Instead of supposing that the general health is lowered and the system poisoned by breathing the emanations from choked drains and cess-pits (causes to which isolated or small groups of cases of typhoid fever seem often traceable) they lay stress upon widespread pollutions of the soil beneath houses and upon variations in the height of ground water of such a kind as to facilitate the entry of emanations from such soil into houses and the production thereby of slowly poisonous effects upon many persons simultaneously. They would thus account for the endemic and epidemic visitations of typhoid fever in particular towns and for their special autumnal prevalence. Speaking on this latter subject in a lecture on "Some Points in the Etiology of Typhoid Fever" Sir Charles Cameron,[10] the medical officer of health of Dublin, said: "Localised outbreaks of typhoid fever can frequently be directly traced to the use of a particular supply of polluted water or milk, but the widespread epidemics of this disease, and even its persistent occurrence in so many towns, must be due to some other cause or causes. For example, in Dublin it was epidemic in 1891-92 and in 1889 it appeared in all parts of the city and adjacent districts." These epidemics, Sir Charles Cameron feels assured, could not be traced to contamination of the water-supply, for in his view "there are few cities in the world with such good water as Dublin fortunately possesses." On the other hand, there is very poor natural drainage owing to the low-lying situation of the city and the soil in very many parts is foul and saturated with decomposing organic fluids. The main cause in Dublin and in other cities of these epidemics of typhoid fever is, Sir Charles Cameron thinks, to be found in these very impure states of the soil. He says he has carefully investigated the subject and is "convinced that typhoid fever is often caused by underground air entering our dwellings" from such polluted soils.

Some years since I received a letter from Dr. Angus Mackintosh,[11] then medical officer of health of Chesterfield, in which, as a result of his experience, he professed his strong belief in the *de novo* origin of typhoid fever. He said: "If not how can those who believe otherwise explain the mystery that enteric fever decreases in proportion as the sanitary condition of any district is improved and that as a direct consequence and in every case. ...... I say, from a lengthened experience in one of the most fever-stricken districts in England, and after carefully investigating 500 cases of that disease, in my capacity of medical officer of health, that 90 per cent. of these could not be traced by me or anybody else to a previous enteric case. The sanitary authority for which I act have borrowed £100,000 from the Loan Commissioners during the last four years for drainage works and water-supply, and by alterations and arrangements in regard to these important items they have reduced enteric fever already in the district to a very small proportion indeed." The moral would seem to be that purity of soil is almost as important as purity of air or water; that bad drainage may pollute both air and water; and that some cases of non-specific fæcal contamination of the latter—and not only pollution by typhoid dejections—may act as causes of typhoid fever. I feel assured that these are safer and sounder doctrines than the narrower views promulgated by ultra-contagionists.

If we look to another disease or rather group of morbid conditions—namely, pulmonary phthisis and tuberculous affections of other organs and parts—a group so common and fatal as to constitute one of the scourges of the human race—there is room for the same uncertainty as to the proportional limits between their *de novo* origin and their spread by means of contagion, though the tendency of late has been to believe in contagion only. The great change of view that has been generally adopted by the medical profession in regard to this matter within the last few years is most remarkable and unprecedented. This change, too, has developed, not so much by reason of fresh and conclusive evidence as to the frequency of contagion in the human subject, but almost entirely upon theoretical considerations and upon unwillingness to believe that a disease caused by a bacillus and capable of being freely propagated experimentally among lower animals inoculated therewith can also arise *de novo*. At the present time it is regarded as quite heretical to think it possible that phthisis can arise independently, while as late as 1896 we find Crookshank in his "Bacteriology and Infective Diseases" (p. 387) writing as follows: "Whether the disease in man is contagious is an open question, though numerous cases of supposed communication between husband and wife, brothers and sisters, have been reported, and Ransome showed that tubercle bacilli were present in the breath in phthisis. On the other hand, the experience in consumption hospitals does not support this view, there being no evidence of the communication of the disease to nurses and hospital attendants." Such, then, have been the remarkable discrepancies in the common view entertained upon this question within a brief period of less than ten years.

At present there is a beneficent enthusiasm for "sanatoriums" in this and other European countries for the relief or the cure of patients who are afflicted with this common and very fatal affection. Phthisis is unquestionably capable of being mitigated—and even cured in many cases where it is not too far advanced—by plenty of fresh air and the best hygienic conditions.[12] This seems to me rather to lend favour to the view that it is commonly an affection produced *de novo* and altogether apart from contagion, as we formerly believed. If good hygienic conditions and improved vitality will lead to the cure of the disease, then low vitality and bad hygienic conditions may have sufficed to produce it. But, it will be said, you forget the presence of the tubercle bacillus. To which I would reply, Have not the experiments made for the artificial production of "Pasteur's septicæmia" almost completely got over this difficulty? The injection of a small quantity of a germ-free chemical irritant into the subcutaneous tissue of a healthy rabbit has made it plain that pathogenic micro-organisms may either be produced by heterogenesis in the focus of inflammation thus caused or else that the germs of common bacilli existing in the healthy animal on which the experiment has been made have been roused, rendered extremely virulent, and have been converted, in fact, into pathogenic bacilli henceforth capable of acting as contagia for the indefinite propagation of this form of septicæmia. Here we have had, over and over again, in the plainest way, the *de novo* production of a contagious disease in which, as in phthisis, bacilli act as the contagia. Why, then, should not an analogous process be similarly possible in the case of phthisis and other tuberculous affections? A bacillus just as specific in its characters as the bacillus tuberculosis makes its appearance also when "Davaine's septicæmia" is produced experimentally. Half a century ago, and less, many conditions now termed "tuberculous" were then spoken of as "scrofulous"; and scrofula was recognised as a condition of low vitality in which inflammations of skin and mucous membranes were common, in association with enlargements of lymphatic glands in the neck and axillæ, and not infrequently chronic diseases of the joints. Now, discarding the old term, we speak of tuberculous joints and tuberculous lymphatic glands, because it is known that the specific bacillus tuberculosis is to be found in the tissues affected, though perhaps nowhere else in the body.

But how, it may be asked, in accordance with present ultra-contagionist views as to the mode by which tuberculous affections are disseminated, are we to explain the isolated occurrence of the tubercle bacillus within the tissues of joints, in the lymphatic glands of the axillæ, or within some of those in the neck? The two generally admitted channels for the entry of such micro organisms into the system are through the mucous membrane of the air passages and that of the alimentary canal, but entry by either of these routes would not satisfactorily account for *their isolated presence in the glands of the axillæ, or in some* of those not infrequently involved in the neck, or within the tissues of the knee or hip-joints.

[10] THE LANCET, June 11th, 1892, p. 1285.

[11] Letter dated August 26th, 1876.

[12] Sometimes, too, even a simple surgical operation, such as drainage of the abdomen in a case of tuberculous peritonitis, will lead to a cure of the patient notwith[illegible] the presence in his tissues of untold l[illegible] to the British M[illegible] o Robson says (Brit. Med. Jour., August 1st, 1903, p. [illegible] seen patients reduced to the last extremity of weakness, where the mesentery was standing stiff with tubercle and the abdomen was swollen to an enormous size, recover completely and be thoroughly restored to perfect health from a condition apparently completely hopeless."

It has for a long time seemed to me that chronic inflammations of lymphatic glands in certain cachectic states of the system (such as we formerly labeled "scrofulous") may be of such a nature as necessarily to produce therein the little nodules which we recognise and name "tubercle." And this same view was very ably set forth in some detail by Mr. (now Sir) Frederick Treves[13] at the International Medical Congress of 1881 in a communication entitled "Tubercle: its Histological Characters and its Relation to the Inflammatory Process, as shown in Tuberculosis of Lymphatic Glands." He points out that all the characters of the nodule known as "tubercle," apart from the bacillus which had not then been discovered, can be referred to a chronic inflammatory process. He says: "The so-called tuberculous process in the external lymphatic glands can often be traced to some simple inflammatory process that implicates the radicles of the gland. Here the first change communicated to the gland is essentially inflammatory and as that change develops in the organ it begins to assume peculiar features." Of course, it would now be said, Yes, what you say may be true, but the irritative or inflammatory influence, the effects of which you recognise, is really due to, and caused by, the presence of the tubercle bacillus. To this it may fairly be rejoined that such a view ignores the real and often obvious cause of the irritation of the gland; that it ignores the general state of the system which pre exists and coöperates; and that it postulates infection without proof as the initial cause of the whole phenomena. But in the absence of any rational or even plausible means of accounting, in accordance with contagionist theories, for the presence of tubercle bacilli in certain lymphatic glands and in these alone, or in some joint and nowhere else in the body, it is, I think, most in harmony with existing knowledge to suppose that this particular bacillus is a product rather than a cause of certain inflammations occurring in lowly vitalised subjects, in just the same way that the appearance of the bacillus of "Pasteur's septicæmia" seems, as Burdon Sanderson put it, dependent "on the intensity of the inflammation itself." The adoption of such a view would go far to explain many difficulties; and the question of the etiology of tuberculous affections would be greatly simplified and brought again more closely into accord with former views.

Quite recently von Behring has been advocating a very different hypothesis.[14] He believes that infection takes place in the main in infancy, through the intestinal canal, and that thereafter the infecting agents lodging in different parts of the body commonly remain latent for years, perhaps for a long series of them He relies in part upon recent investigations showing the high percentage of cases in which tuberculous lesions of some kind are to be found at *necropsies or demonstrated* during life by *tuberculin and* other means; and in part upon his own researches demonstrating that tubercle bacilli can, in infancy more especially, easily pass from the intestine into the lacteals and thence into the blood. He discredits the now commonly accepted views as to the frequency of infection through the lungs. It seems true that he has proved the possibility of infection with tubercle or other bacilli in the manner he indicates. I, on the other hand, have proved the possibility of their *de novo* origin. He postulates long periods of latency after systemic infection, hard to be believed; and ultimately requires agencies for waking the tubercle bacilli into activity, just such as I suppose may be adequate for calling them into being—namely, malnutrition and conditions of lowered vitality howsoever produced, though among such factors impure air and inadequate or improper food must take an important place.

It would, of course, be an easy step to recognise the extreme probability that the conditions which had sufficed for the appearance of the characteristic bacilli in the glands and in the joints might also obtain in the lungs. We might then return to something more like the sober views that prevailed concerning the etiology of phthisis only a few years ago when the affection was freely recognised as generable in the individual, altogether apart from contagion, and contagion was supposed to take only a limited share in the production of the disease. This seems the more rational and most warranted view to take. It is one which would tend to *lay stress* upon the need for prevention as well as cure, but it would not encourage the view that the disease could be exterminated, or even very largely diminished, by the provision of "sanatoriums" and by efforts to minimise the risk of contagion. I merely mean to imply that, in my opinion, contagion is as much overrated as genesis is underrated and that our notions concerning prevention must not be too much centred upon the mere elimination of contagion.

I will only briefly refer to one more disease, but to one having several points of agreement with the affections last considered and concerning which much discussion has been taking place of late. I allude to that terrible affection leprosy which is generally admitted to be contagious only in a low degree and under the influence of very special conditions. Being an affection so slightly contagious and yet so widespread in different countries the question naturally arises, Is it not also generable *de novo?* It was in the past freely believed to be so, but since 1874, when Hansen discovered that a bacillus was always to be found in the tissues affected, there has been a growing antagonism to this view owing to the yearly increasing importance of bacteriological work and the ultra-contagionist views that bacteriologists seem invariably to favour. Formerly the malady was commonly ascribed to the conjoint influence of bad hygienic surroundings, poverty, and exposure, together with deficient and improper food, more or less putrid. Of these conditions it would seem quite possible that some peculiarities in food may have been, and may still be, most potential in favouring the development of the disease. It seems to me that Mr. Jonathan Hutchinson has distinctly strengthened this view and brought forward some valuable evidence in support of his own position that badly preserved and semi-putrid fish is one of the most important factors pertaining to this category. At all events, whether his conclusions are to be accepted as correct or not, his personal researches in South Africa and in India in collecting evidence on this very important subject, involving as they must have done so great an expenditure of time and labour, are surely worthy of the highest praise.[15]

The conclusion to which he has come in regard to the relative frequency of the spread of the disease by contagion and its *de novo* origin is very similar to that arrived at by the leprosy commissioners in India. Their verdict, given in 1890–91, was that the influence of contagion was "as small as, or even rather less than, in the case of tuberculosis,"[16] and that in the great majority [illegible] *de novo.* This I regard as a [illegible] one quite explicable in accord [illegible] it would be absolutely repudiated by many, perhaps by most, ultra contagionists, as may be gathered from an article on Leprosy in the *Quarterly Review* for April, 1903, from the pen of a medical writer. Referring to this verdict of the commissioners in India and reflecting perhaps the prevailing medical opinion of to-day this writer says (p. 397): "But *did any one* of the commissioners or does anyone with knowledge of the subject contend that tuberculosis arises *de novo?* What induced the commissioners to come to the conclusion as to the *de novo* origin of leprosy is a psychological puzzle and it is difficult to see how the supporters of such an hypothesis account for the presence of bacilli in the leprous patient. Are we *to suppose that these micro-organisms* arise spontaneously?"

In the debate which took place at the Royal Medical and Chirurgical Society Mr. Hutchinson met with the same kind of intolerance and there was a similar ignoring of facts which would have permitted his critics to find less difficulty in accounting for the presence of the bacillus in a case in which leprosy had originated *de novo.* They should not have forgotten the specific bacillus of "Pasteur's septicæmia," which can be produced at will by skilful investigators with the aid *not* of semi-putrid food but of a few drops of putrid blood It was not even absolutely necessary, as I have shown in this communication, that they should believe in a *de novo* origin of the bacillus itself; it was still less necessary that they should require its presence to be demonstrated in the bad fish or other food; and it was absurd, as I take it, gravely to attempt to shunt the real question by the gratuitous statement that "the origin of the germs of disease was probably in the remote geological past." It is a pity the able author of this sentiment did not give us some hint as to the mode of production of these germs in the past and what his warrant was for using the word "probably" in such a connexion.

[illegible]

slight in tuberculosis.

What I have said in regard to the possible *de novo* origin of tuberculosis would, in fact, with slight variations be applicable in regard to leprosy. It cannot be denied that the disease is to a slight extent contagious but there is much evidence to show that in the main it arises *de novo*. There is certainly nothing unreasonable in the supposition that putrid fish, or other bad food of like kind, may carry into the system bacteria and the toxic products which they have formed, and that the continued influence of such bodies may in some persons act as irritants and either engender or awaken organisms in this or that tissue having the characteristics of the leprosy bacillus, just as the boiled dilute liquor ammoniæ injected into the subcutaneous tissue of a guinea-pig or a rabbit produces, even within a few hours, swarms of the bacillus met with in "Pasteur's septicæmia," or as two or three drops of putrid blood in the same situation may give rise to the appearance throughout the body of swarms of the more distinctly specific bacilli which suffice for the indefinite propagation of "Davaine's septicæmia."

In any case the importance of diligently seeking after the cause of leprosy must be admitted and Mr. Hutchinson[17] is obviously right when he says: "It cannot be necessary to insist that the prevention of leprosy is a work of far greater beneficence than is the mere provision for the care and comfort of the leper. ...... Not only in India but in South Africa, the West Indies, and many other of our colonies, the saving in money as well as the mitigation of human suffering would be immense if the leprosy question were once settled. Large sums are now benevolently devoted to asylums for lepers. My conviction is strong that one-tenth of the sums thus annually expended would, if devoted to discovery of the cause, render these establishments unnecessary and save their cost for all time."

Manchester-square, W.

THE TREATMENT OF PULMONARY TUBERCULOSIS BY HIGH-FREQUENCY CURRENTS (LOW POTENTIAL) AND INTRALARYNGEAL INJECTIONS OF ANTISEPTICS.

BY J. CUNNINGHAM BOWIE, M.B., C.M. GLASG., D.P.H. F.P.S. GLASG.

HAVING been for some years interested in the treatment of phthisis it occurred to me to try whether electricity could influence the toxicity of tuberculin or the toxins of the micro-organisms usually found associated with tubercle bacilli in the pulmonary lesions. I found that the passage of a current of electricity through the toxins considerably modified or annulled their toxicity and that the greater the volume of electricity used the more quickly this was accomplished. From this I concluded that electricity might be of value in the treatment of phthisis or of other diseases where bacterial toxins had to be contended with and it appeared to me that the volume of electricity was an essential factor. In order to pass this volume of electricity into the body I relied upon the high-frequency current. Further, I believed that pathological changes in the tissues must necessarily bring about a difference in their resistance to the current and that a low tension would obviate or lessen any danger which might arise in consequence. To meet this difficulty it was essential that in the working of any high-frequency apparatus it should be possible to regulate frequency, voltage, and ampèrage, and accordingly with the aid of an electrical engineer I designed a machine possessing these advantages and a description of the apparatus which I have used in my experiments appeared in THE LANCET of May 2nd, 1903, p. 1247.

In the administration of the current the electrodes are applied directly to the thoracic walls and are made to embrace the situation of the lesion and the pulmonary tissues around it. Having concluded that the subject is a victim of phthisis pulmonalis it is essential to consider, not only the clinical history of the case and the nature and extent of the lesion, but also the effect which the disease has produced upon the general health of the patient. One must also take into consideration the physique, temperament, and habits of the subject. For instance, chronic alcoholism is in itself almost a barrier to successful treatment. By taking these into account it is possible to form a more accurate estimate of the patient's powers of resistance to the tubercle bacilli and their toxins and to the toxins of a mixed infection. To appreciate this will materially assist in giving a prognosis upon the case. This will become more evident when it is considered that some cases of phthisis pulmonalis which at first might appear to be hopeless will respond favourably, while others of apparently less grave nature will not be so amenable to treatment. Some consumptives have a greater toleration to the toxins of the tubercle bacilli than others and as a consequence it is often found that with an extensive lesion the body has suffered comparatively little, while another case with a more limited lesion will have suffered to a greater extent. When the disease has assumed a chronic character it might be concluded that the case would be more amenable to therapeutic measures than one which is running a more acute course, but this is by no means always the case, because in the more chronic form of phthisis the toxic products absorbed from the lesion have had a longer time in which to damage cell metabolism.

If 28 or 48 cubic centimetres of almond oil containing six centigrammes of iodine, 24 centigrammes of thymol, 0·5 gramme of menthol, and 1·5 cubic centimetres of beechwood guaiacol be injected intralaryngeally we apply to the lesion and the toxins, to the bacilli and the other micro-organisms of the mixed infection, a solution of antiseptics of the above strength. These antiseptics with the oil are partly absorbed by the lymphatics of the lungs. That portion which becomes volatile saturates the residual air of the lungs.

By the combined action of high-frequency currents and antiseptics I believe it is possible to bestow upon the organism a stronger power of resisting the toxins of the tubercle bacilli and other micro-organisms which may be associated with them, with the result that the vital powers of the organism become raised and the pulmonary tissues approximate to their original degree of resistance. That the tubercle bacilli lose their virulence is evident from the changes which occur in their morphological characters—i.e., they become thin, attenuated, and stain but feebly. Thus the body can be given a more or less complete immunity to the toxins of the lesion for the greater part of the 24 hours every day. The under-mentioned cases are cited as examples in which the patients were submitted to the combined treatment by intralaryngeal injections of antiseptics and low-tension high-frequency currents. The injections were administered twice daily and the electricity once. The ampèrage of electricity passed through the pulmonary structures varied from 300 to 800 milliampères at a pressure of from 50 to 70 volts, and the time of each application was from ten to 20 minutes. The arrest of the lesion is brought about more quickly by this combined treatment than by the use of antiseptic oils alone, and my experience shows that the high-frequency currents promote its healing.

CASE 1.—The patient was a female, aged 35 years, married, and the mother of five children, the youngest being eight months old. For over a year she had been troubled with a cough and expectoration (the latter especially in the morning), night sweats, and loss of flesh and vigour. The sputum contained tubercle bacilli. The family history was tuberculous. There were a pulmonary lesion on the left side in the supra- and infra-clavicular regions, dulness, and increase of vocal fremitus. The respiratory murmur was harsh and jerky, a few clicking and moist râles were audible, and the voice was husky at times. The larynx was congested but there was no paleness to indicate a tuberculous process. The temperature was 99° F. On alternate days 250 milliampères of electricity were passed through the larynx and the voice quickly regained its normal tone. The patient was under treatment for eight months and now feels quite strong. Her gain in weight was ten pounds. The temperature is normal. Physical examination of the chest points to arrest of the lesion.

CASE 2.—The patient, a male, aged 19 years, complained of cough with expectoration, hæmoptysis, and loss of flesh and vigour His height was 6 feet and his weight was 10 stones 6 pounds The thorax was well formed, there was restricted movement on the right side The family history was tuberculous There were a pulmonary lesion on the right side immediately below the middle line of the clavicle, dulness, and increase of vocal resonance, the respiratory murmur was harsh and hesitating and mucous râles were audible, the sputum contained a few tubercle bacilli The patient was under treatment for nine months, but some time prior to the expiration of this period the cough and expectoration had ceased Physical examination of the chest does not reveal any evidence of the lesion The patient feels quite strong, his gain in weight is 20 pounds

---

[17] The Times, May 25th, 1903.

CASE 3 —The patient was a male, aged 31 years He complained of cough, with expectoration, night sweats, loss of flesh and strength and impaired appetite His evening temperature was 102° F He attributed his condition to an attack of influenza 18 months previously His family history was tuberculous There were a pulmonary lesion on the right side in the supra and infra clavicular regions flattening and dulness There was increase of vocal fremitus, bronchial breathing, clicking and mucous râles were audible The sputum contained tubercle bacilli, numerous and vigorous The patient was under treatment for ten months At the expiration of six months the expectoration had ceased and there was but little cough whilst the temperature was normal He now feels quite well, has gained in weight 18 pounds and from physical examination of the chest it is difficult to indicate the lesion

CASE 4 —The patient, a female, aged 19 years, complained of irritating cough and slight expectoration which often contained traces of blood, she attributed her condition to an attack of influenza nine months previously Her family history was tuberculous There was a pulmonary lesion in the right side, movement was restricted in the infra clavicular region, there was perceptible dulness and the respiratory murmur was rough and halting, in the inter scapular regions a few mucous râles were audible The sputum was centrifugalised and a few tubercle bacilli were detected The duration of treatment was seven months and at the end of this period the patient had no cough or expectoration The temperature was normal She feels quite well and has gained in weight ten pounds Physical examination of the chest does not reveal any evidence of the lesion

Cardiff

SOME CASES OF DILATATION OF THE BRONCHIAL TUBES AFTER MEASLES

BY THEODORE FISHER M D, M R C P LOND

PHYSICIAN TO OUT PATIENTS TO THE BRISTOL ROYAL HOSPITAL FOR SICK CHILDREN AND WOMEN PATHOLOGIST TO THE BRISTOL ROYAL INFIRMARY

IN the post-mortem room from time to time one meets with dilatation of the bronchial tubes in children The dilatation may be widely distributed through both lungs or it may affect only one lung, or perhaps only one lobe of a lung which may be the upper or the lower lobe In other cases one lobe in each lung may show marked dilatation of the bronchial tubes, in which case it is generally both lower lobes that are affected Occasionally when the dilatation of the bronchial tubes is limited to one lung or to one lobe of a lung a definite local cause in the form of some obstruction to the bronchus or one of its main divisions may be found For example an enlarged caseous bronchial gland may in rare instances give rise to obstruction I have met with one case but only one of marked character due to this cause In other cases a foreign body may be found and possibly such a cause for dilatation of the bronchial tubes is more common than the evidence of the post mortem room might lead one to suppose The fact that a foreign body is not found at the necropsy does not prove that such a body was never present For example, in a case recorded by Mr O A Morton[1] which I saw clinically and in the post mortem room there was a history of a small steel body having entered the air passages three years before and the child's illness had dated from that event, yet at the post-mortem examination no trace of the foreign body or other cause of obstruction could be found in the bronchus of the affected lung the bronchial tubes of which were dilated from apex to base The steel body must either have rusted away or have been expectorated without attracting attention In other cases where sweets or portions of nuts enter the air passages solution or disintegration may possibly occur In connexion with the mention of sweets, an illustration may be given of the difficulty of obtaining a trustworthy history, even from intelligent parents, of the entrance of a foreign body into the air passages In a little girl brought to the Bristol Royal Hospital for Sick Children and Women for chronic lung trouble I found what I considered to be obvious evidence of dilatation of the bronchial tubes in the lower lobe of the left lung, yet careful questioning of the mother failed to elicit any facts suggesting the entrance of a foreign body into the air passages On the next visit, however, the mother apologised for having forgotten that about nine months previously when the child was sucking an "acid drop" the sweet had gone the wrong way" Violent fits of coughing followed which left the child very exhausted A medical attendant was called in four days later who found the child feverish and decided that it was necessary to keep her away from school for a week The troublesome cough from which the girl suffered had dated from that time

While some cases of dilatation of the bronchial tubes in children are due to pressure upon a bronchus or upon one of its divisions by a caseous gland and others to blockage of the bronchus or of one of its divisions by a foreign body, some cases undoubtedly occur as a sequel of broncho-pneumonia Curiously enough the last four instances of dilatation of the bronchial tubes of this character met with by myself have apparently been occasioned by broncho pneumonia occurring as a complication of measles In all the cases the children were said to have been free from any symptoms of disease in the chest until they were attacked with measles Within a few weeks or months of the onset of measles death occurred and dilatation of the bronchial tubes in varying degree was found

The first and least marked case occurred where death took place earlier than in the other cases This case was met with at the Bristol Royal Hospital for Sick Children and Women when I was taking the work of the senior physician, Dr C Elliott

CASE 1 —A girl, aged three years, was brought to the hospital with broncho pneumonia four weeks after an attack of measles and was admitted The child was obviously very ill, the pulse was 170, the respirations were 72 and the temperature was 100° F Numerous sharp râles were heard over both sides of the chest but especially over the right side, and we were doubtful whether we had a case of broncho pneumonia or of acute tuberculosis Nine days later the child died At the necropsy the greater part of the right upper lobe was found to be solid and the bronchial tubes everywhere were slightly but definitely dilated giving a sieve like appearance to the lobe Patchy consolidation was present in the middle and lower lobes and the affected areas showed similar dilatation of the bronchial tubes In the left lower lobe there were very small scattered areas of broncho-pneumonia but no obvious dilatation of the bronchial tubes was present

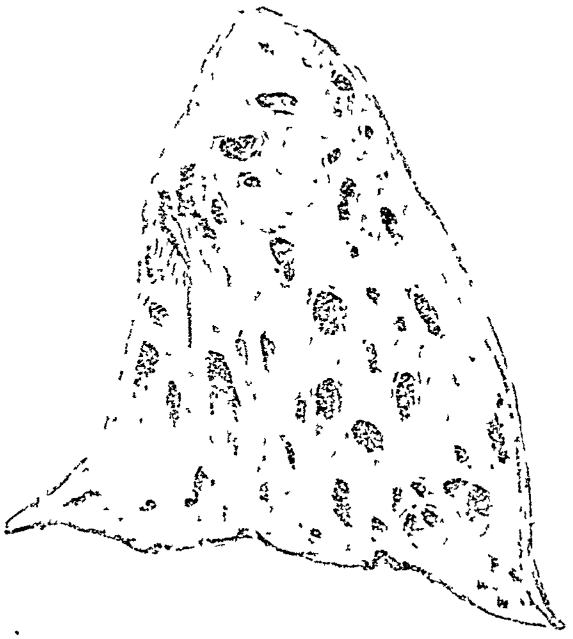
In the next case the dilatation of the bronchial tubes was very much more marked

CASE 2 —A boy aged one year and eight months, was brought to the out patient department of the Bristol Royal Hospital for Sick Children and Women on Jan 26th, 1903 The child had the pale puffy face not uncommonly seen in children with chronic lung trouble The fingers were slightly clubbed and the breath was offensive. The physical signs of the lungs showed a somewhat dull note over the whole of both lower lobes and marked bronchial breathing was present On inquiring into the history it was found that the child had suffered from measles at the age of eight months and had been affected with cough since that time This fact, together with the aspect of the child and the clubbed fingers and offensive breath led me with some confidence to enter in my notebook 'dilated bronchial tubes after measles' with recent broncho pneumonia. The child died four days later and the necropsy was performed by Dr Bertram Rogers Both lower lobes were found to be adherent to the chest wall and somewhat contracted On section of the lungs the bronchial tubes were seen to be everywhere greatly dilated and their walls to be thickened. Some of the cavities were large enough to hold a medium-sized pea. The upper lobes showed no dilatation of the bronchial tubes but small patches of broncho-pneumonia were present On microscopical examination the lower lobes showed no general fibrosis. There was considerable increase of fibrous tissue with destruction of alveoli immediately around the dilated bronchial tubes but for the most part the intervening lung substance was unaffected except that recent broncho-pneumonia was present. A very noteworthy feature of this case, which I have seen in other cases of dilated bronchial tubes in children, was great thickening of the blood-vessels, mainly of the external coats

---

[1] THE LANCET, July 14th, 1894 p 78

FIG. 1.



Section of the right lower lobe in Case 2. The left lower lobe was similarly affected.

The two next cases were met with in the post-mortem room of the Bristol Royal Infirmary.

CASE 3—A boy, aged one year, was admitted into the Bristol Royal Infirmary on Nov. 21st, 1902, under the care of Dr. J. E. Shaw. The patient had suffered from an attack of measles four months before and since that time a cough had always been present. He had been worse during the week before admission. Widespread bronchophony was present on the right side of the chest, but loudest over the upper lobe, where cavernous sounds were also present. The temperature oscillated between 100° and 102° to 103° F. The child died 15 days after admission. At the necropsy marked dilatation of the bronchial tubes was present in both lungs, but chiefly in the upper lobe of the right lung and to a less extent in the lower lobe of the left lung. The cut surfaces of the lungs were dotted over with cavities of various sizes, some of which were large enough to hold a good-sized pea, and cavities of this size were situated even close under the pleural surface of the right upper lobe. Some patches of consolidation were also present.

In the following case the dilatation of the bronchial tubes was of the same character but much less extensive.

CASE 4—A boy, aged 17 months, was admitted in the Bristol Royal Infirmary, under the care of Dr. H. Waldo, with raised temperature and rapid respiration and pulse, and he died a few hours later. He was said to have been ill since an attack of measles three months previously. At the necropsy the left lower lobe was found to be adherent to the chest wall and the pleura was greatly thickened where the lung was adherent to the diaphragm, measuring in some places fully a quarter of an inch in thickness. The bronchial tubes throughout the lobe were markedly dilated and their walls were thickened. In some places thickening of the smaller blood-vessels could also be seen. Amongst the dilated tubes were patches of recent consolidation The rest of the lung and the whole of the right lung were quite healthy and free from dilatation of the bronchial tubes.

Earlier in the year 1902 I had met with another very marked case of dilatation of the bronchial tubes in the lower lobes of the lungs of a boy aged 14 years On looking up the clinical notes I found that it was merely stated that the boy had been ill for nine years. I therefore paid a visit to the parents in order to obtain further information. After I had mentioned in the form of a question that the notes said that the boy had been ill for nine years I received the reply "Yes, and he had measles five times." Further questioning seemed to show this to be true, since the attacks of measles occurred either when friends or his brothers or sisters were suffering from the disease and also when measles was prevalent in the school he attended.

In the only other two well-marked cases of dilatation of the bronchial tubes occurring in children met with by me in the post-mortem room during recent years in which no local cause for the dilatation could be found an attempt was made by me to find the parents and to question them Measles had not been mentioned in the clinical notes in one case but an attempt to find the parents showed that they had left Bristol and no further information could therefore be obtained. In the other case nothing more definite in the way of history could be obtained from the mother of the child than that he had been delicate from birth and had always had a cough. The mere history that either of these children had suffered from measles would, it is scarcely necessary to remark, have been of no value. It is only when chronic or subacute pulmonary trouble definitely dates from an attack of measles and dilatation of the bronchial tubes is found that we can reasonably attribute to measles any share in the causation of the dilatation. In the cases which have formed the subject of this paper a connexion between measles and the dilatation of the bronchial tubes seemed to be clear. That the observation of this connexion is a new one I do not pretend to suggest. The fact that broncho-pneumonia which follows measles may occasion dilatation of the bronchial tubes has been recognised for some years. It has been the occurrence of four, I think I may say five, successive cases of dilatation of the bronchial tubes in which the cause appears to have been measles that has seemed to me to be worthy of note. Perusal of the papers of Carr[2] and Sharkey[3] would seem to show that my experience is exceptional. But exceptional experience sometimes emphasises facts which otherwise might have escaped our notice.

[3] Sharkey. St. Thomas's Hospital Reports, vol. xxii., p. 33

FOUR CASES IN WHICH A CYSTIC OVARIAN TUMOUR, WHICH WAS NOT MALIGNANT, DEVELOPED AFTER A SIMILAR GROWTH OF THE OVARY ON THE SAME SIDE HAD BEEN REMOVED.

BY JOHN D. MALCOLM, M.B., C.M., F.R.C.S. EDIN.,
SURGEON TO THE SAMARITAN FREE HOSPITAL.

CASE 1.—*In February, 1893, I showed to the Obstetrical* Society of London a cystoma which I successfully removed from a woman, aged 48 years. Fifteen years earlier Mr. J. Knowsley Thornton removed from the same patient two very adherent ruptured ovarian tumours. These had papillomatous growths both inside and on the outer surface of the cysts and the peritoneum was red and granular. A small flat growth in the peritoneum to the right of the abdominal incision was removed. Another similar growth just below the inferior angle of the wound had an irregular piece hanging down into the peritoneal cavity and the pendulous part of this was removed. The patient was in good health for 13 years after the operation, although not so strong as before. She menstruated regularly until she was 40 years old—that is, for nearly seven years after the first operation. The periods then ceased and did not return. In 1891 the patient began to suffer from flatulence and discomfort. In the following year the abdomen enlarged whilst the rest of the body emaciated and there was constant and increasing nausea. I operated on Jan. 14th, 1893, and removed a multilocular cystic tumour. There were extensive and close adhesions deep in the pelvis and the uterus was so embedded in the neoplasm that there was great difficulty in defining and separating it. The whole tumour was removed and some of the cysts contained papillomatous growth but there was no sign of papilloma outside the tumour. The patient recovered and was alive and well three years later, being then 51 years old. A letter sent to her lately has been returned by the postal authorities.

CASE 2.—In the second case Mr. Knowsley Thornton *performed a double ovariotomy for cystomata* in November, 1889, much deep enucleation from the broad ligaments being necessary. The patient recovered and was in good health for nearly six years, after which she again showed symptoms of an abdominal tumour with emaciation. After the first operation the periods, which had always been scanty, appeared at long intervals, from six to nine and, on one occasion, 12 months. There was never more than a show. The last was nine months before the second operation and the patient's age was then 52 years. On Jan 28th, 1896, I removed a multilocular cystic growth. It was covered in part by adherent omentum and there were many adhesions to adjacent tissues. The lower part of the mass was embedded in the broad ligament but the enucleation was not very deep. Many ligatures were required to arrest hæmorrhage and a drainage tube was inserted but was removed on the next day as there was then no discharge escaping. At the end of a week, Feb. 3rd, the temperature was 99° F. in the vagina in the morning. Three days later it rose to 102° in the evening and there was tenderness at the lower end of the wound which was quite healed superficially. Early on the 7th the wound opened and there was a discharge of thick red blood to the extent of half a pint or more. The discharge within 24 hours became insignificant in amount. The temperature at once fell to normal and the patient gradually regained her health and went home six weeks after the operation. The wound did not finally heal, however, until many ligatures escaped. The last came away after nearly a year and the wound then quickly closed. During the greater part of this time the wound was either closed or had only a very minute opening. The patient was alive and well nearly six years after the second operation and her age was then 57 years. In this case also a letter of inquiry sent recently has been returned.

These are the only cases of the kind that I have seen in my own practice[1] or that I remember having seen in the practice of those with whom I have been associated until I operated in December, 1901, and January, 1902, on the two patients whose histories are related below. A case in which I removed a multilocular cyst from an attachment to the left side of the fundus of the bladder differs from the others in important details. The growth was quite separate from the left ovary, which was healthy, and from the right broad ligament, from which an ovarian tumour had been removed 20 years before.[2] The case is unique in my experience.

CASE 3.—In this case Mr. Knowsley Thornton removed a cystic tumour of the right ovary in 1895 On that occasion a very deep enucleation from between the layers of the broad ligament was necessary. In January, 1898, I *examined the patient and found nothing abnormal. In* December, 1901, Dr. James Alexander of Paignton asked me to see her again. She was then 63 years of age and was a short, very stout woman, with a small, feeble pulse. A few weeks earlier she had a slight discharge of blood from the vagina with some serous fluid which stiffened the linen. The discharge continued for a few days and then ceased but it returned after a short time. On making an examination I found a tumour of the size of a fœtal head at term to the right of, and closely attached to, the uterus, the whole being firmly fixed in the pelvis. The uterus was high up on the left side, being almost out of reach of the finger. Its cavity was three inches in length and the sound passed easily except that it was difficult to get at the os. There was no pain. I expressed the opinion that the tumour was malignant and that its removal was impossible. I was not quite certain about it, however, and I requested a consultation with Sir John Williams who saw the patient with me on the following day. In the interval the bowels were cleared by a laxative and an enema, with the result that at the second examination the tumour was much more mobile and the uterus was lower down so that it could be more easily examined. Sir John Williams thought, and I agreed, that the tumour might be non-malignant and that an exploratory operation should be performed. The possibility of the coexistence of malignant disease of the uterus and an innocent tumour was discussed but there were not sufficient grounds for making such a diagnosis and both of us had seen cases in which the development of an ovarian tumour after the menopause was associated with the return of a red uterine discharge although no malignant disease existed. On Dec. 16th, 1901, I opened the abdomen in the presence of Sir John Williams. There were no adhesions to the back of the scar. A tumour was exposed deeply buried in the broad ligament on the right side, the side from which Mr. Knowsley Thornton had removed an ovarian tumour. There was an adhesion, about two and a half inches in diameter, of small intestine and omentum to the upper part of the peritoneum covering the growth. After letting out some of the fluid contents of the tumour *by means of a trocar and cannula I cut through its* peritoneal covering and enucleated it with difficulty, having to divide many bands of tough tissue which fixed the growth deeply in the pelvis and to the uterus. When the tumour was removed it was easy to bring the opening of the cavity in which it had been contained to the lower end of the incision in the abdominal wall, where it was secured, the sac being packed with iodoform gauze wrung out of corrosive sublimate solution and the upper part of the abdominal incision being closed in the usual way. The adhesions of intestine and omentum to the peritoneum covering the tumour were not divided. During the operation the patient's pulse was very feeble and Mr. Henry Davis, who gave the anæsthetic, had to be careful not to push it. The patient rallied well and there were no alarming symptoms during the first 24 hours. Flatus passed freely from the rectum and the abdomen was soft and not distended. The temperature rose to 101·6° F. in the vagina and the highest pulse was 90. There was some vomiting during the afternoon and a good deal of fluid escaped from the wound. At first it was bright red but very soon it became a light pink serum. On the day after the operation the abdominal condition continued good and flatus passed downwards well. Towards the evening the patient became very restless and in the night the temperature rose to 103°, the pulse rising to 124 and becoming very feeble. On the second morning after the operation the iodoform gauze was removed from the wound and two drainage-tubes were inserted. There were a few small healthy blood clots on the gauze and evidently there had been no hæmorrhage of importance. The plug smelt strongly of iodoform. During the second day after the operation the temperature rose to 104°, the rate of the pulse increased, and its volume was very small. The breathing became rapid towards evening and the patient gradually sank and died.

---

[1] These two cases were shortly referred to in a paper on 26 cases in which a second abdominal section had been performed. Transactions of the Medical Society of London, vol. xx.

[2] Transactions of the Obstetrical Society of London, vol. xli., p. 266.

There was no examination of the body and it is difficult to say exactly what was the cause of death. The operation was a severe one but death was not from shock and there certainly was not enough blood lost, either during the operation or afterwards, to account for the fatal issue. In many respects the conditions seemed like those due to septic infection. I do not think the capsule round the tumour extended so near to the rectum that the wall of the latter could be damaged or so thinned that septic matter would pass from the bowel to the sac packed with gauze. But there was a considerable adhesion of small intestine to the upper part of the capsule and although the peritoneum was taken off the tumour with the adhesions undisturbed it is possible that septic contamination may have taken place from the adherent bowel. I do not think, however, that septic infection occurred in this way nor do I think that iodoform poisoning had any influence in bringing about the death of the patient. It seems to me that one of the chief causes was cardiac debility. The extreme stoutness of the patient and her age and feeble condition made me anxious beforehand as to her power to withstand the effects of surgical treatment. After the operation it was impossible to place her in any position except on the back and nearly flat, because every attempt to raise her pressed the abdomen and chest together and at once caused respiratory distress. On the other hand, the dorsal position together with the feeble heart action tended to produce congestion of the bases of the lungs, and difficulty in breathing was a very urgent symptom on the second day after the operation. The onset of this difficulty was quickly followed by the death of the patient.

CASE 4.—This patient was operated on 11½ years before I saw her by the late Dr. A. W. Edis on June 29th, 1891. He removed both ovaries on account of a cystic tumour of the left one "of the size of a child's head" and a papillomatous growth like a small wart on the right ovary. Dr. Edis's representatives kindly placed his notes at the disposal of Dr. J. W. Browne of Holland-park avenue, to whom I am indebted for many of the details of the patient's history. At the first operation "some suspicious villous-looking spots" were left owing to the collapsed condition of the patient and Dr. Edis stated at the time that he feared they might give trouble. The patient was very well for five years after the operation and had no uterine hæmorrhage After five years she suffered from irregular red discharges with pelvic pain and a small hard tumour was discovered close to the uterus The patient was seen from time to time by Sir John Williams, Dr. Browne, Dr. J. C. Uhthoff of Brighton, and others, but operative treatment was not advised because the growth was quite small and seemed to be closely incorporated with the uterus. Towards the end of 1901 there was a rapid increase in the size of the tumour, its cystic nature became obvious, and the patient began to lose flesh. It was thought necessary to attempt its removal and Sir John Williams asked me to see the patient with him and Dr. Browne on Jan. 9th, 1902. The patient was a stout, rather short woman, 62 years of age She was thus only one year younger than the patient whose operation proved fatal but she was more active, looked younger than her age, and had a fairly good action of the heart. The abdomen was distended by a large cystic growth and there was a hernia of the scar nearly eight inches long by about four inches wide standing quite one and a half inches out from the level of the adjacent abdominal wall and much more prominent when the patient stood up The hernial sac contained bowel which evidently came round the right side of the tumour, the abdomen being dull on percussion all over the left side as high as the ribs, which were pushed out, whilst on the right side of the scar the note was resonant In the pelvis the tumour was felt behind, and to the left of, the vagina, pushing it forwards and to the right. Sir John Williams passed a sound into a fairly small uterus a year before, but the womb was drawn up quite out of reach of the finger when I saw the patient. I operated on Jan 16th, 1902 The hernia was opened and some bowel and omentum which were adherent to the opening into the sac were separated, one large patch of raw surface on the small intestine being carefully sewn over. The tumour was still covered by a broad band of omentum which was adherent to the peritoneum over the cyst and over the bladder. When this was separated the growth was exposed and tapped. Some large cysts were evacuated and then it was fairly easy to enucleate the growth from under the peritoneum in the upper part of the abdomen, but in the pelvis the connexions with neighbouring structures were very close, especially those to the back of the uterus and vagina. The whole growth was got out and the mouth of the cavity from which it was removed was fixed to the lower end of the abdominal incision, a rent in its upper part being first closed by means of a silk suture. Before fixing the mouth of the sac and closing the abdomen I pared the edges of the hernia so as to expose the muscle on each side, and the greater part of the wound was sewn up with a single layer of sutures. In dealing with a hernia I generally bring the parts together in several layers, but as the operation was prolonged and severe I used one layer in this case in order to save time. An opening was left in the lower end of the wound and the sac which had contained the tumour was packed with iodoform gauze. After the operation the patient had some difficulty with the bowels, and the bladder, which had been a source of irritation from the date of an operation on the urethra 25 years earlier, continued to give trouble. Before the operation the skin over the sacrum was very tender and a bedsore formed and required much attention. The packing was taken out of the sac on the third day and two rubber tubes were put in. These were gradually shortened and finally removed on the twelfth day after the operation. The patient gradually recovered and the bedsore healed. When she was able to walk the bladder and bowel conditions rapidly improved and the patient's health became very good. I saw her with Dr. Browne on August 14th, 1903; the wound showed no stretching of the skin, but the fascial edges were not together, especially at the lower end. By keeping the parts well supported, however, the patient has no trouble from the wound. The urethra, which required frequent dilatation before the second operation and which occasionally discharged pus freely, was quite comfortable after the patient was able to walk about until July, 1903. There was then some pain on micturition. In August there were two small tender red spots just inside the meatus urinarius and I found a stricture about three quarters of an inch higher up the urethra. There were two slight hæmorrhages in June and July, 1903. The patient's health has much improved in the last few months.

In these cases the tumours removed were not to be distinguished from ovarian cystic growths. They were, in fact, cystic growths of some portions of ovarian tissue which were left behind at the first operations. In Cases 1 and 4 there was something of the nature of a secondary deposit which was not removed but it is almost certain that this shrivelled up and did not give rise to any trouble. The new growth in all the cases developed in the broad ligaments where the ovarian tissue would be if any were left behind. Such cases are rare. Sir John Williams has kindly permitted me to state that Cases 3 and 4 are the only instances of the kind he has seen. But perhaps the really remarkable point about them is that they are not more common. When a surgeon enucleates a tumour deeply embedded in the broad ligament he has no guide to the direction in which he must divide the tissues except the outline of the tumour, and although in the great majority of cases by removing the tumour completely the whole ovary will be taken away also, yet it would not be surprising if minute pieces of ovarian tissue were occasionally left behind and if new growths developed in them. The fact that this does occasionally happen is important and a recollection of the possibility of it may help the surgeon to a correct diagnosis in circumstances pointing strongly to the view that a malignant recurrence exists. In all of the foregoing cases malignancy was suspected and the operations were undertaken with the understanding that it might not be possible to remove the tumours.

Cases 3 and 4 illustrate another somewhat rare point—namely, that an innocent growth developing in the neighbourhood of the uterus after the menopause may bring about discharges of blood from the endometrium, just as ovarian tumours growing before the menopause may induce a very free menstruation which may lead to an erroneous diagnosis of uterine fibroma.

There are other cases somewhat analogous to those recorded above in which also the conditions can be explained only by assuming that a minute portion of ovarian tissue is inadvertently and perhaps unavoidably left in the body when the surgeon secures and divides the broad ligament or separates adhesions between an ovary and adjacent structures

That it is sometimes impossible completely to remove an ovary is demonstrated by a case in which Mr Alban H G Doran removed both ovaries and the uterus for fibroma [3] Dr Cuthbert H J Lockyer examined the specimen and "found a distinct piece of ovarian tissue or 'accessory ovary' in one ovarian ligament close to the uterus," so that if an attempt had been made to cure the patient by removal of the ovaries the "accessory ovary" would have remained in the pedicle and probably the development of the tumour would have gone on unchecked as in the following case

On Oct 30th 1897, I performed hysterectomy for the removal of a fibroid tumour after the arrest of its growth had been attempted by the extirpation of the ovaries I found a piece of ovarian tissue attached to the left cornu of the uterus quite easily recognisable by the naked eye The surgeon who operated first is a well known man and a skilful operator and I was surprised that he had apparently overlooked a very obvious piece of ovarian tissue in the course of an operation in which the complete removal of the ovary was essential to success Recently a case occurred in which I did both operations I thought at the first that I had completely removed both ovaries on account of inflammatory mischief and adhesions Menstruation did not cease, however, and on reopening the abdomen for the cure of a hernia I found a body of the size of a filbert nut in the right broad ligament The greater part of this consisted of a Graafian follicle and there was no doubt as to its nature When the follicle burst a small firm body was still felt This piece of ovarian tissue was not very close to the uterus It was left because I did not tie and divide the broad ligament low enough It occurred to me that a very minute portion of ovarian tissue, if left in the body, might enlarge to some extent by the development of ova in it Whether this is possible or not, the case proves conclusively that a very small piece of ovarian tissue may become a mass of considerable size when a follicle develops There must be many cases similar to this last for it is often very difficult to tie and to divide a broad ligament sufficiently low down to insure complete removal of the ovary

The following case seemed to me to show that in separating adhesions portions of ovarian tissue may be detached and left in the body Both ovaries were inflamed and very adherent After separating them from adjacent structures I exposed the broad ligament on each side and removed the ovary and tube by a method recommended by Dr Charles B Penrose, professor of gynæcology of the University of Pennsylvania [4] By this plan the surgeon ties and divides each broad ligament close to the uterus and also as far out in the pelvis as possible. This secures the principal vessels and there are not any of any size in the part of the broad ligament still unligatured so that it may be cut without fear of serious hæmorrhage I pointed out to the onlookers at the operation how completely I was able to remove the ovaries by this plan Nevertheless, the patient menstruated regularly and only recently at the age of 44 years, eight years after the operation, the periods have shown signs of stopping I thought that in this case I must have separated some portion of ovarian tissue whilst dividing the adhesions and so left it in the body, but Dr Lockyer's observation shows that even by the plan adopted some ovarian tissue might remain close to the uterus In another case in which I thought that I had removed completely two small but very adherent and inflamed ovarian tumours menstruation persisted In still another case a patient was brought to my house suffering so acutely from a swelling in the right side of the pelvis that I advised her to go straight to a nursing home I diagnosed an extra uterine fœtation but thought it possible that an abscess had formed in connexion with the Fallopian tube A few days later I removed the right ovary and tube a gestation sac being found in the latter The left ovary and tube were swelled and matted together by old inflammation and they were removed also The uterus was heavy and congested and much of its surface was raw from separation of adhesions I thought it might be wiser to remove it also, but the operation was already a long and severe one and in consultation with Mr J Kingston Barton, who brought the patient to me, it was decided to leave the uterus I thought that I had removed the ovaries and tubes completely in this case, but in order to do so I had to tie the tissues very near to the left cornu of the uterus and there was considerable difficulty in arresting hæmorrhage there The periods continued after the operation, at first irregularly, but after a time they became regular The uterus remained large and heavy and there was a white discharge between the periods I found also after a time a small painful swelling far out on the left side of the pelvis A year later it was decided to remove the uterus and to examine the tender part. The abdomen was opened and the swelling consisted of a thin walled cyst of about the size of a cob nut closely resembling a hydatid of Morgagni and completely buried in adhesions There was also some membranous tissue which I have no doubt was part of the inflamed ovary or tube incompletely removed a year earlier, although at the first operation I was not aware that any portion of either of them was left behind

In the Transactions of the Obstetrical Society of London for 1902 [5] Mr Doran recorded a case in which he removed a cystic tumour of the right ovary 14 years after Dr Robert Barnes removed a cystic adenomatous growth of the left ovary A deep enucleation of the base of the neoplasm was necessary when Mr Doran operated and he was not sure whether the Fallopian tube was removed or not It was thought that all the ovary had been removed and Mr Doran was surprised to find that the patient continued to menstruate Two years later she bore a child Mr Doran concluded that "some ovarian tissue must have been left behind free from any trace of cystic adenoma which is almost certain to recur if not thoroughly extirpated " Mr Doran quoted several other cases in which pregnancy occurred when it was supposed that both ovaries had been excised I have no doubt that it is impossible sometimes to be sure that the ovaries are completely removed, so that from time to time other cases will crop up in which a new but not malignant growth of the ovary develops after an operation in which it is supposed that complete extirpation has been effected In the majority of such cases the fact that the ovary has not been completely removed will be shown by a continuance of menstruation This indication was absent in the third and fourth cases I have recorded probably because the patients had passed the climacteric being respectively 57 and 51 years old at their first operations I have already noted that the return of the discharge which occurred in these case may tend to mislead the practitioner But such a return of the discharges is not to be expected in every case of this kind For instance it did not occur in Case 1 in which the periods ceased about halfway between the two operations In Case 2 the periods did not cease but the intervals were greatly prolonged between the operations

AN ADJUNCT TO UTERINE IRRIGATION IN PUERPERAL FEVER

BY DAVID WATSON, M B C M GLASG ,
HONORARY SURGEON TO THE GLASGOW HOSPITAL FOR WOMEN; DISTRICT SURGEON TO THE GLASGOW MATERNITY HOSPITAL ASSISTANT SURGEON TO THE GLASGOW LOCK HOSPITAL

THE treatment of the septic uterus by irrigation is attended with certain dangers which induce many practitioners to adopt it with hesitancy and it frequently happens that during the first few days of a puerperal fever the uterine douche is withheld in the hope of being able to do without it Meantime the septic process may become more deeply seated and beyond the reach of antiseptic solutions in the uterine cavity It is in the early stages that irrigation is most likely to be useful, hence the importance of being able to adopt it with confidence immediately that its use is indicated One of the dangers is associated with the poisonous character of the solution employed, as the uterus post partum presents a surface capable of rapidly absorbing any watery solution coming into contact with it Professor O R Marshall, Dr W McGregor Young and others have pointed out the danger of mercurial poisoning, the danger of carbolic acid is not less obvious and on this account when these antiseptics are adopted the usual practice is to complete the douching with plain boiled water. But the danger which I believe to be most imminent does not depend on the antiseptic used but on the fact that watery solutions are employed and the uterus is left wet. This water may act prejudicially in two ways: (1) by dissolving the toxins and so promoting their rapid absorption into the circulation; and (2) by assisting the growth of micro-organisms. Washing out a septic uterus is not uncommonly followed within an hour or two by a rise of temperature with or without a rigor and other symptoms of increased toxæmia and this can be prevented by the removal of all trace of water from the uterus after the douche. To expose the cervix and to swab out the uterus with dry gauze (as is my practice in curetting) would be inconvenient and the method I adopt is, after expressing as much of the douche solution as can be got rid of in that way, to inject into the cavity of the uterus one ounce of glycerine containing 3 per cent. of formalin. This solution is quite innocuous and unirritating and in addition to its powerful antiseptic action it removes all water from the uterus and its use prevents any rise of temperature following the douche. To inject the glycerine all that is required is a glass syringe of one ounce capacity with a small piece of rubber tubing attached to its nozzle for connecting with the Budin or Bozeman catheter which has meanwhile been left in the uterus. Needless to say, the whole procedure is carried out with the strictest aseptic precautions. The following two cases show in a marked way the benefit of this treatment.

---

[3] Harveian Lectures THE LANCET Feb 7th 1903 p 352
[4] Annals of Surgery July 1896
[5] Vol xliv

CASE 1.—A woman had a normal labour and an uneventful convalescence until the eighth day when the nurse of her own initiative and without reason gave a vaginal injection by means of a faulty enema syringe. On the evening of the ninth day the temperature was 102° F. and the patient was flushed and restless On the tenth day at 12.30 P.M. the temperature was 101°; the uterus was douched with a weak formalin solution. The patient had a rigor at 3 P.M.; her temperature was 103°. From the eleventh to the thirteenth days the temperature was 99·5° in the morning and 101° in the evening. On the fourteenth day the patient was not so well: her morning temperature was 100·2°. She was douched with perchloride of mercury solution, 1 in 3000, followed by plain boiled water; then one ounce of glycerine and formalin (3 per cent.) was injected into the uterus and a vaginal tampon of wool saturated with the same glycerine solution was left *in situ* for three hours. The temperature 20 minutes after the injection had fallen to 99·2°. Her evening temperature was 99·8°. On the fifteenth day her morning temperature was 99·8°. A tampon of glycerine and formalin was inserted which was removed in three hours and her temperature was then normal. Thereafter the uterine condition gave no trouble but in spite of preventive measures abscesses formed in the breasts. On opening and packing these with iodoform gauze recovery was uninterrupted.

CASE 2.—This patient was confined on June 11th, being attended by a midwife. On the fourth day the midwife was sent for on account of abdominal pain, restlessness, and delirium. She gave the patient four pills (opium?). At 8 P.M. when seen by me the patient had great flatulent distension, pain and tenderness in the lower part of the abdomen, and a temperature of 101° F. and a pulse of 144. She was ordered a purgative and four grains of quinine every four hours. I gave her a uterine douche of perchloride of mercury, followed by plain boiled water. Her temperature three hours later was 103°. On the fifth day at 10.30 A.M. her temperature was 103°. I gave her a uterine douche as before and followed it with one ounce of glycerine and formalin. At 1.30 P.M. her temperature was 103°. At 8.30 P.M. her temperature was 103° and her pulse was 132. (The best result was not got from this injection through my neglect to express from the uterus the retained water before injecting the glycerine.) On the sixth day, at 12 noon, her general appearance was much brighter; her tongue was clean and moist; her temperature was 99·8° and her pulse was 98. At 7 P.M. her temperature was 100·2° and her pulse was 100. On the seventh day the patient was restless and delirious during the night; her temperature after midnight was 101·2°. At 12 noon her temperature was 100° and her pulse was 108 I gave a douche and injection as before but was careful to empty the uterus before injecting the glycerine. Immediately after the douche her temperature was 99·8° and her pulse was 88. At 8 P.M. her temperature was 99·6° and her pulse was 84. On the eighth day her temperature was normal and her pulse was 86. The patient described herself as feeling perfectly well. Her further progress was uninterrupted.

Both of these were clinically severe cases. In Case 1 the rigor and rise of temperature following the first douche made me hesitate to use it again unless this risk could be minimised. The same effects following the first douche in Case 2 confirmed my former observation but having the glycerine at hand next day I had no hesitation in proceeding again to wash out the uterus. The injection when properly carried out has an immediately good effect but the benefit is still more evident on the day following. With regard to the use of vaginal tampons of wool saturated with the glycerine and formalin they seemed to have an effect in lowering the temperature but my experience in Case 2 indicates that they are unnecessary and there is the risk of their insertion forcing matter from the vagina into the cervix. If used they would require frequent renewal. In conclusion, I would suggest that after douching a septic uterus the uterus should be emptied by expression and one ounce or more of glycerine, with 3 per cent. of formalin, should then be injected into the cavity with the double object of extracting water from the uterus and of applying a strong, but unirritating, antiseptic to its surface. When this precaution is taken one need have no hesitation in having recourse to washing out the uterus whenever there is evidence of its septic infection, with considerable hope of cutting the process short after two or three injections.

Glasgow.

A CASE OF

CUTANEOUS NEURO-FIBROMATOSIS IN WHICH NEWLY FORMED NERVE FIBRES WERE FOUND IN THE TUMOURS.

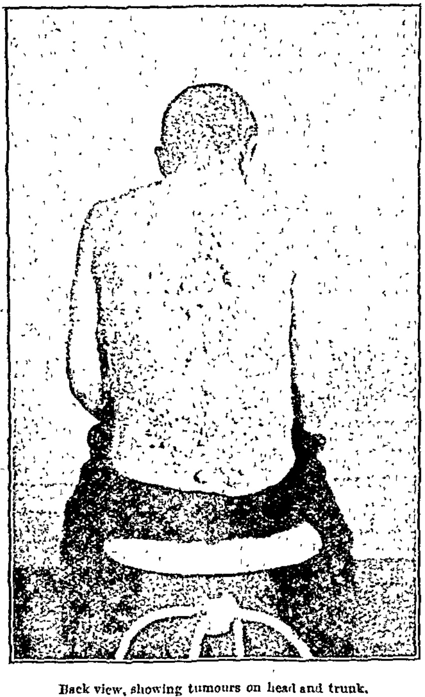
BY ARTHUR WHITFIELD, M.D., M.R.C.P. LOND., M.R.C.S. ENG.,

ASSISTANT PHYSICIAN IN CHARGE OF THE SKIN DEPARTMENT, KING'S COLLEGE HOSPITAL; PHYSICIAN TO THE SKIN DEPARTMENT, GREAT NORTHERN CENTRAL HOSPITAL.

THE group of rare morbid conditions to which this case belongs was first collected by von Recklinghausen in 1882. Before this time the several forms of lesion found were kept apart under different names. Thus the single, large, pendulous, circumscribed or diffuse tumours of a limb were known as "elephantiasis" (one form only), the multiple small tumours of the skin were called "molluscum fibrosum," while those on the nerve trunks were termed "false neuromata" Von Recklinghausen showed that all these conditions were different phases of the same morbid state and from his classical description of the generalised affection, characterised by the presence of tumours on the nerves, tumours on the skin, and patches of pigmentation, it is often termed "von Recklinghausen's disease." It is, however, not invariable for all these cardinal symptoms to be present and one finds cases in which the development of the cutaneous tumours is well marked while none are to be found on the palpable nerve trunks; almost invariably the pigmentary changes are present but these also may fail in a certain proportion of cases. It then becomes a question whether one can be certain of the diagnosis of neuro-fibromatosis from the cutaneous tumours alone. Several observers of cases in which this was the only symptom have expressed doubt as to the connexion of the tumours with the nerves in all cases but there seems to be reason to believe that the failure to find this connexion results rather from faulty technique. The case related and investigated here was that of a male patient in the wards of St. Mary's Infirmary and I am greatly indebted to my friend Dr. A. H. Robinson, the superintendent of the infirmary, for placing the case at my disposal.

The patient, aged 50 years, was a short and rather badly developed man but with no thyroid deficiency. He talked indistinctly and was slow in answering, apparently rather from feeble intelligence than from deafness. He walked with a rather spastic gait, especially marked in the right leg, and while in the wards he had several slight epileptiform attacks. Little could be obtained from him in the way of history but he volunteered the fact that his father had one similar large lump on the back of his shoulder. There was no consanguinity between his parents. As regarded himself he was certain that the tumours were not present when he was born but that they had developed in his youth and he thought that new ones still occasionally appeared—at any rate, they had done so recently. The scalp, face, and trunk were thickly covered with softish tumours varying in size from that of a pea to that of a walnut, and there were also a few on the right side of the tongue and beneath the mucous membrane lining the cheeks. A few were scattered about the arms and legs and one or two on the backs of the hands, but the fingers and toes and the palms and soles were free. It was not possible to trace any arrangement in the tumours suggesting their running on the course of nerves and there were none to be felt on the palpable nerve trunks. There were no areas of elephantiasis nor were there any pigmented patches, but there were two patches of white hair on the scalp of long duration. The tumours were all more or less adherent to the skin over them but were freely moveable over the subjacent structures and many could be pushed backwards and forwards through a kind of hole in the skin giving the sensation of reducing a small hernia. The colour was of a darkish red and in many instances very large sebaceous openings, occasionally blocked with comedones, could be seen on their surface. There was no pain felt at any time during their formation or existence and they were not especially tender on pressure. The illustration (see Fig. 1) shows the distribution sufficiently well to render detailed description unnecessary further than stating that the front aspect resembled that of the back.

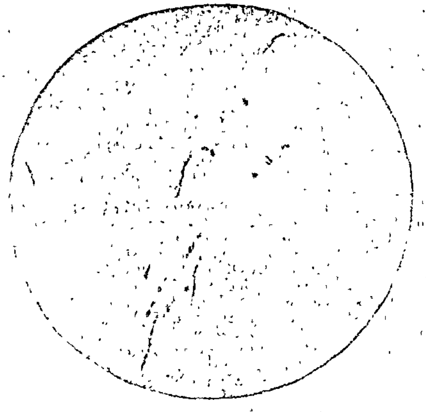
FIG. 1.



Back view, showing tumours on head and trunk.

The patient readily consented to allow me to excise one of the tumours for examination and for this purpose I selected a small one on the back. On section the tumour was of a reddish-brown, translucent appearance and was well defined both on its superficial and on its deep aspects, so that it had a tendency to separate from its surroundings during the process of hardening. It was immediately dropped into Müller's solution and sections were made on completion of the fixation by freezing the piece in the Müller's fluid itself. By this method it was thought that all danger of interfering with the subsequent staining reactions by the various fluids used in embedding in celloidin would be avoided. The sections thus obtained were treated with a reliable specimen of the Kultschitzky-Wolters stain kindly given to me by Dr. J. Purves Stewart, some of them being also stained for ordinary histological details. The tumour was found to consist of a feebly fibrillated matrix in which were embedded very numerous spindle and branched cells; it was extremely vascular and showed the occasional inclusion of sebaceous and hair follicles. In places definite concentric arrangements were seen, and in those sections stained specially for nerve fibres these were always found to occupy the centres of the whorls thus formed. In every section of the tumour which was suitably stained fairly numerous nerve fibres were found, usually rather widely separated from one another as if by proliferation of the endo- and peri-neurium themselves. A point of great interest was that these nerve fibres in most instances showed a very well-marked beading exactly similar to that described by Purves Stewart as characteristic of newly developing nerve fibres, and on showing them to him he at once corroborated my opinion that they were such in reality (see Fig. 2). The tumour was therefore more than a simple overgrowth of the nerve sheaths and actually gave evidence that a true new formation of nerve fibres was taking place.

FIG. 2.



Microscopic appearance of tumour.

On searching the literature of this rare disease I find that there is only a limited number of cases in which nerve fibres have been demonstrated within the cutaneous tumours, in most cases their connexion with the nerve being inferred from the presence of similar tumours on the palpable trunks.[*] On this account cases in which tumours have not been felt on the nerve trunks have been separated off and ascribed to proliferation of the sheaths of the epidermic appendages. Westphalen found the nerve fibres in more than one case, Kyrieleis found them in three cases, Hürthle in four cases, and Kriege in two cases with Weigert's method but not with osmic acid. The last observer states that there was hypertrophy of the primitive fibrils but no true hyperplasia. Soldau in examining ordinary skin nævi or moles found a very rich supply of nerve fibrils supplying them and would class all nævi as neuro-fibromata, an absolutely untenable position in my opinion, as Unna, Gilchrist, and I have shown that these are undoubtedly epithelial structures, though of course they may be dependent on some nerve abnormality. Payne, Rolleston, and Alexis Thomson apparently did not find any nerve fibrils in the cutaneous tumours and Payne was of opinion that in his case the tumours were not related to nerves. There seems to be a general consensus of opinion that the tumours, even granting that they are growths of the nerve sheaths, are not accompanied by any new growth of nerve fibre itself, but I think in the light of this case that this opinion will have to be modified. I am quite aware, of course, that this contention must stand or fall by the accuracy of Purves Stewart's work and deductions, but having seen a good number of his specimens demonstrating what he claims to be various stages in the development of the new fibre I certainly regard his work as completely convincing.

Bentinck-street, W.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

NOTE ON A CASE OF PURPURA HÆMORRHAGICA.

By WALTER H. HAW, M.R.C.S. ENG., L.S.A.

THE case of purpura fulminans reported in THE LANCET of June 20th, p. 1740, appeared just at the close of a case of the above disease which had occurred in my practice, unfortunately with a fatal result. In my case the history pointed clearly to the causation—namely, a combination of immersion in cold sea-water, fright, shock, and sea-sickness Which of these antecedents is to be regarded as the *fons et origo mali* I cannot presume to determine, but fright and shock appear to have been present in greatest degree. The very interesting part of the case is that the patient, who was a boy, was looked upon by his parents as possessing the very essence of good health; he was of sturdy build, strong, hearty, and had never had an illness in his life until the onset of this his fatal attack immediately following the accidents which will be mentioned.

On June 13th, 1903 the patient was brought to me by his father who stated that he could not make out what was wrong with his boy, as he seemed to be "falling to pieces." He had been in his usual good health until 14 days previously, when while in a canoe on the bar at the entrance to the harbour he was capsized and in addition to a very cold wetting he had received a great fright, for it is a very dangerous spot He appeared none the worse, however, and a week later, while descending a hill on a bicycle, he ran into a herd of cattle and had a fall, hurting himself rather severely but only to the extent of bruises. Apparently he recovered from this without ill result and some days later with his father he crossed the bar of the harbour for the first time in his life in an ordinary fishing boat, a feat which requires unlimited confidence and nerve. His father said that he suffered severely from fear and later from sea-sickness during the whole time they were at sea. After this final experience he was not himself and suffered first from cramps and then from epistaxis. When I first saw the patient he was pallid, waxy-looking, and had a peculiar flush on the cheeks, and there was a blood clot blocking the left anterior nostril. On his neck, chest, abdomen, arms, and thighs there were numerous discrete purpuric spots, the largest seen not being greater in diameter than a buckshot. He also suffered from insomnia, fatigue after slight exertion, a constant shivery sensation, tachycardia, anorexia and a slimy feeling in the mouth. The tongue and conjunctivæ were pale, the temperature was normal, and there was dulness in the splenic area as far forward as the edges of the cartilages. On the next day epistaxis commenced and I plugged the left nostril with a petticoat plug The motions were black. On the 15th the spots were more marked on the abdomen and the chest The plug had at once stopped the hæmorrhage and I did not remove it until the next day, when the bleeding began again and the plug had to be re inserted. On the 17th there had been no further bleeding. On the 18th epistaxis began from the right nostril which was successfully plugged. Both nares were now blocked and breathing had to be accomplished by the mouth. The anæmia was profound. On the 19th matters were going on well and continued so until July 3rd when epistaxis again started and necessitated plugging. At this time I first noticed puffy œdema of the face, the hands, the legs below the knees, and the feet, but there was no albumin in the urine. I may mention here that during each attack of epistaxis the cardiac action became quite violent, pulsation being visible over the front of the chest and also along the carotids, and also that before I discontinued my visits on June 21st the splenic dulness had disappeared. On July 3rd it had returned and the patient's general condition was evidently more grave than it had ever been. The purpuric spots also had broken out afresh. Later vomiting began, chiefly of blood clots which had been swallowed during the attacks, but it was checked by tincture of iodine. There was no further epistaxis but when I visited the patient on the 4th he was moribund and he died peacefully from heart failure in my presence. It is noteworthy that the œdema had greatly lessened.

These were the salient features in this case and I think that the etiology is very clearly indicated but what pathological condition was brought about by the precedent factors is difficult to determine. The tachycardia might suggest an irritation of the sympathetic system. I may add, in conclusion, that the blood in the later stages was very pale and watery but it still clotted fairly firmly

Knysna, Cape Colony.

TAPEWORM AS A CAUSE OF CHOREA.

By RONALD D. HODGE, M.B., CH.B. GLASG.

IN view of Mr. J. A. W. Pereira's clinical note on Tapeworm as a Cause of Chorea which was published in THE LANCET of Sept. 19th, p. 824, I think the following case will prove of interest.

On August 10th 1903, I was sent to visit a young girl, aged nine years, whom I found resting in a semi recumbent position with flushed cheeks, circumoral pallor, and a somewhat anxious look. She had been ill since the previous day and on examination of the chest I detected a slight to-and-fro friction sound between the tricuspid and apex regions of the heart. This sound was markedly increased on steady pressure with the stethoscope. There was also a long, soft, blowing systolic murmur heard most distinctly at the apex and also well heard over the tricuspid and pulmonary areas and conducted into the left axilla and to the lower angle of the left shoulder-blade behind. On the pulmonary area the second sound was reduplicated. The apex beat was within the vertical nipple line in the fourth left interspace. Her temperature was 102·5° F. and her pulse was 120 per minute. There was no history of rheumatism but there were a doubtful history of "growing pains" and a distinct one of chorea 14 months previously when she was attending the out-patient department of a public hospital. So far as the patient's mother knew there was no cardiac complication at that time. Although there were no choreic movements present I thought it as well to warn the girl's friends that the chorea would be likely to return, which it did in five days when the pericarditis had disappeared and the temperature and pulse had fallen to nearly normal. On the second day after the choreic movements became evident there were slight pain and swelling of both knees and ankles lasting for two days. The movements became gradually worse until the patient was unable to feed herself, but she was still able to swallow, while if questioned she made an effort to answer but would finish up with a fit of either crying or laughing. By Sept. 14th the girl was so much improved that she was able to get up and to go about.

On the 21st the mother informed me that the girl had that morning passed several pieces of tapeworm and on inquiry I learned that 15 months previously when attending hospital for chorea she was also troubled with the parasite, in proof of which I was shown the remains of the emulsion of filix mas which had been ordered; also that 18 months previously pieces of tapeworm were voided unaccompanied by chorea. Unfortunately, when the cestode was passed on the next afternoon the head could not be found, although the part examined had broken off well up towards the head, judging from the very small size of the segments. The anthelmintic was repeated in two days' time but although the motions were carefully searched the head was not found. Considering that the treatment was the same as that which proved successful in dislodging a tapeworm from an adult woman three months before it is possible that the head escaped notice.

Now what is the prime etiological factor in this case?

The various combinations were: (1) 18 months previously the cestode was present; (2) 15 months previously the cestode and chorea were present; and (3) six weeks previously pericarditis, endocarditis, chorea, rheumatism, and the cestode were present. I might say in reference to the cardiac complications that there did not seem to be any increase of dulness towards the left side, but dulness extended to the right border of the sternum, whilst there was slight dulness at the base of the left lung in the axillary line which, with the friction sound in that region, existed for several days.

I am indebted to my principal, Dr. R. Bishop, for permission to report this case.

Manchester.

AN ANTENATAL CASE OF MEASLES.

BY JOHN R. GIBSON, M.D., F.F.P.S. GLASG.

IN Dr. J. W. Ballantyne's book on "Antenatal Pathology and Hygiene" he says in the chapter on Fœtal Measles: "No instance has been placed on record of a fœtus suffering from measles, *the mother escaping*, although having been subject to infection," &c. The following case therefore deserves to be published.

Over a year ago I attended a woman in her third confinement. The birth was easy. The nurse when washing the child called my attention to some raised dull-red spots on both buttocks. It then struck me that this rash might be a syphilide but I did not venture any opinion as the two previous children were very healthy and the character of the parents was above reproach. On the next morning the uncertainty was cleared up, for I found the child covered with a typical measles rash and suffering from suffusion of the eyes, nasal catarrh, and bronchitis and, in short, all the cardinal symptoms of measles. The child recovered in the usual period and without any medicinal treatment. The temperature ranged from 99° to 100° F. The mother made an uninterrupted recovery and showed not a single symptom of measles. When the baby was eight months old the other two children took the measles but the baby did not. The mother had had measles when a child.

UNIVERSITY COLLEGE HOSPITAL.

A CASE OF TRAUMATIC PNEUMOTHORAX.

(Under the care of Mr. RICKMAN J. GODLEE.)

FOR the notes of the case we are indebted to Mr. J. A. Smyth, house surgeon.

The patient, a female, aged 21 years, was admitted into University College Hospital on March 28th, 1903, under the care of Mr. Rickman J. Godlee, having been knocked down and run over by a van which passed completely over the chest. On admission at 8 P.M. she complained of great pain down the left side of the chest and had obvious respiratory embarrassment. There was marked cyanosis of the face. Upon the left side of the chest the third, fourth, fifth, and sixth ribs were fractured just external to the nipple line, the chest wall falling in with each inspiratory act. There was marked tenderness with some fulness over the clavicle on the right side but no fracture could be detected. The breath sounds were plainly audible upon both sides of the chest; there was a constant rattle in the throat with each expiration, due to accumulation of mucus which she was unable to cough up. The heart's impulse was in the fifth space three and a half inches from the midsternal line; the heart sounds were normal. The pulse was 100. No injury to the spine was detected; there was no paralysis of the lower extremities. At 9 P.M. (one hour after the accident) the cyanosis of the face was more marked and she was extremely restless. Surgical emphysema was now present over the clavicle and the upper part of the chest on the right side. At 10 P.M. surgical emphysema was also present on the left side of the chest extending downwards as low as the fourth costal cartilage and upwards into the neck. Strapping was now applied to the left side of the chest but had to be removed ten minutes later as it increased the pain.

On March 29th at 4 A.M. movement of the chest was markedly deficient upon the right side upon which she was now lying. At 10 A.M. surgical emphysema had extended upwards in the neck as high as the jaw, a resonant note being obtained on percussion over the neck. Movement was now entirely absent upon the right side of the chest and there were typical signs of pneumothorax. The left side of the chest moved freely, recession of the ribs being less marked. The cyanosis and respiratory embarrassment were now intense, the respirations being 40 per minute. The heart's impulse was displaced to the left, being in the fifth space external to the nipple. The liver could not be felt. A trocar and cannula was now inserted into the chest in the eighth right intercostal space in the scapular line, a tube being attached to the end of the cannula and dipping into a bottle containing sterilised salt solution. On removing the trocar there was immediately a rush of air escaping from the pleura during each respiratory act. Directly the salt solution began to be drawn up into the tube a clip was applied, the cannula being packed round with cyanide gauze and retained in position. The cyanosis immediately lessened and the respirations dropped to 28 per minute. Upon auscultating the chest the breath sounds were audible over the whole lung area on the right side. At 7 P.M. the breath sounds had again become inaudible and respiratory embarrassment and cyanosis were again marked; the clip on the tube was removed and air again escaped from the pleura during respiration, after which the clip was reapplied.

nds returning at

less air escaping

than on the two previous occasions, and on moving the cannula the end could be distinctly felt to strike against the lung.

On March 30th as the breath sounds were quite audible the cannula was removed from the chest. There was dulness posteriorly at the lower part of the chest on the right side. The temperature, which had been about 100° F. since admission, rose towards evening to 103·2°. The respirations were 38. On April 1st a double crop of herpes appeared upon the chin and the lower lip and the expectoration was viscid, small in amount, and tinged with blood. The temperature had fallen to 101°. Movement at the right base was deficient; the percussion note was dull upon the right side below the angle of the scapula. The breath sounds were bronchial in character at the right apex and tubular in the fourth intercostal space anteriorly, below which level they were absent, vocal fremitus and vocal resonance being also absent. On the 15th pulsation was marked in the second, third, and fourth interspaces to the right of the sternum, extending one and a half inches to the right of the lateral sternal margin. The heart's impulse was not palpable but the heart sounds were best heard in the fourth space two inches from the midsternal line upon the left side. The heart sounds were normal. A resonant note was obtained on percussion over the whole area of normal cardiac dulness to the left of the sternum.

Five weeks after the accident the patient was discharged from the hospital and was sent to a convalescent home where she remained for a fortnight. During the latter part of this time she was subject to attacks of dyspnœa on the least exertion. On May 26th the physical signs had undergone but slight alteration. The cardiac signs remained unchanged. Movement on the right side was deficient, especially at the base. The percussion note was impaired at the right apex anteriorly and dull below the third interspace. Posteriorly the dulness was absolute below the angle of the scapula. The breath sounds were bronchial in character in the first, second, and third spaces anteriorly, below which level they were absent. Bronchophony and whispering pectoriloquy were well marked at the apex. No moist sounds were present. Posteriorly the breath sounds were bronchial in character down to the angle of the scapula, below which level they were completely absent.

Remarks by Mr. SMYTH.—The object in publishing this case is to draw attention to the great relief afforded to the patient by the tapping of the chest. It seems difficult to believe that the pressure in the pneumothorax could be greater than the atmospheric pressure, since otherwise air would not have passed into the pleura and, therefore, the relief obtained seems to me to be explained in the following manner. That it was noticed that the large volume of air escaped from the pleura during expiration and that clipping the tube prevented the fluid from being sucked into the chest during inspiration to replace this volume of air. Therefore, it follows that the pressure in the pneumothorax was now below atmospheric pressure and consequently the lung was more free to expand. Subsequently, when more air was sucked in through the rupture in the lung, the pressure in the pneumothorax again became atmospheric and the symptoms returned, being again relieved by unclipping the tube during expiration. This relief would have been impossible if a trocar had been inserted, since then the pressure in the pneumothorax would never have been below atmospheric pressure. The change in the physical signs later was undoubtedly due to absorption of air and collapsed lung being drawn over the heart.

I am indebted to Mr. Rickman Godlee for permission to publish the case.

LIVERPOOL WORKHOUSE HOSPITAL.

A CASE OF RUPTURE OF THE RIGHT KIDNEY INTO FRAGMENTS; OPERATION; RECOVERY.

(Under the care of Dr. WILLIAM ALEXANDER.)

FOR the notes of the case we are indebted to Dr. A. T. M. Dodd, senior resident medical officer.

A man, aged 47 years, was admitted into the Liverpool Workhouse Hospital on Oct. 20th, 1902. He stated that while drunk he fell heavily on to the edge of a bucket three days previously to admission. He complained of severe pain in the right flank (aggravated by movement and during micturition), of passing a considerable quantity of blood per urethram, and of frequent vomiting. On examination a slight bruise in the right flank was visible. There was slight abnormal dulness. There was no apparent swelling but excessive tenderness on pressure. He was in a very collapsed condition. His temperature was 101°F. The urine was passed frequently; sometimes it was loaded and intimately mixed with blood, with clots of blood at the end of micturition; at other times the urine was comparatively clear. Laudanum stupes were applied to the abdomen and flank and one-sixth of a grain of morphia was given by hypodermic injection to relieve the pain. A large quantity of blood was passed later in the evening and an ice-bag was substituted for the laudanum stupes. Five minims of liquid extract of hamamelis were given every four hours and small quantities of milk and brandy were given at frequent intervals. The patient had a restless night and was passing almost pure blood, evidently with great pain. On the 24th he complained of retention. A No. 9 soft catheter was passed without difficulty and urine was drawn off containing numerous small clots; apparently the urethra was blocked by blood clot. During the next day there was slight improvement in his general condition but the hæmorrhage continued unabated. On the 25th the bladder was washed out twice. After the second washing the patient had a rigor, the temperature rising to 102·6°. Five grains of quinine in cachets and five grains of urotropine were given thrice daily with good result. On the following day there was a marked improvement—the urine was only tinged with blood. During the next eight or nine days he steadily improved, the temperature remained normal, the blood in the urine diminished daily, and the pulse was getting stronger. The diet at this time consisted of one pint of beef-tea, three pints of milk, and one egg. On Nov. 7th, after partaking of his usual quantity of beef-tea, the patient vomited. The previous symptoms again developed with great rapidity. Five minims of solution of perchloride of mercury and two minims of tincture of opium were given hourly to relieve the vomiting. The diet was confined to milk only. Laudanum stupes were applied and suprarenal extract in tabloid was given thrice daily. During the next few days there was slight improvement, but as the hæmaturia still continued two ounces of pure hazeline were left in the bladder after the washings had drained away. At this time the general condition of the patient was anything but encouraging, the pulse was weak and rapid, and the temperature ranged between 100° and 102°. There was occasional vomiting and he was taking very little nourishment. On the 16th Dr. Alexander, after much persuasion, obtained the patient's consent to an operation.

On the following morning chloroform was administered and an incision was made parallel to, and about one and a half inches above, the iliac crest on the right side and the kidney was exposed. On opening the capsule it was found to consist of fragments of kidney substance mixed with blood clot. The greater part of the clot and pieces of kidney were removed. The cavity was washed out and packed deeply with cyanide gauze. The patient stood the operation well. There was considerable leakage of urine from the wound during the day which necessitated the dressing being changed three times. In the evening he had slept for about two and a half hours after a quarter of a grain of morphia had been given hypodermically. He appeared to be comfortable (except for pain on movement) and had passed naturally 21 ounces of urine during the afternoon. During the succeeding days the dressings were changed frequently on account of the continual leakage of urine and four ounces of brandy were given daily. The temperature ranged between 101° and 102·4°; the patient took nourishment well, slept well, and rapidly improved in his general condition. Eight days after the operation a large slough was removed from the wound which was found to consist of breaking-down kidney substance. After this day the leakage of urine from the wound ceased; the urine passed per urethram was free from all traces of blood and the wound healed rapidly. The patient continued to improve, passed an average of about 40 ounces of urine daily, and put on flesh. He was able to get up and to be about six weeks after the operation.

Remarks by Dr. ALEXANDER.—The above case of ruptured kidney is remarkable for the great extent of the lesions, the entire absence of local signs of disturbance, although there were considerable retention and extravasation of bloody urine in the flank, and the tendency to spontaneous recovery until the attack of sickness produced a recurrence of the hæmorrhage. The hæmorrhage ceased when the cavity was packed with gauze and the torn kidney gradually healed and all the urine secreted was passed per vias naturales. Delay in operating was due in the first instance to the promise that the symptoms gave of spontaneous cure and afterwards to the reluctance of the patient to be operated on in his weakened condition.

Medical Societies.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

Primary Chancre of the Tongue.—Large Bile Cyst of the Liver.

A MEETING of this society was held on Oct. 27th, Mr. ALFRED WILLETT, the President, being in the chair.

Mr. R. CLEMENT LUCAS showed a case of Primary Chancre of the Tongue. The patient was a married man, aged 35 years. He had a family of five children and was a farrier by trade. He was admitted into Guy's Hospital on Oct. 20th for a sore beneath his tongue. About five weeks before he noticed two little white spots beneath his tongue; these extended and formed a sore. He was unable to account for the sore except that in his shop the men were accustomed to smoke the first pipe they saw lying about. The sore extended across the frænum and forward nearly to the tip of the tongue and was almost symmetrical. The edges were slightly undermined. It had a greyish surface and the mucous membrane around was red and inflammed. The sore was very painful and tender. There were enlarged glands beneath the jaw on the left side extending nearly from the symphysis to the angle. They were firm and adherent to the deeper structures but not to the skin. On the skin there was a brownish papular syphilide to be seen on the arms, chest, and abdomen, and there were a few on the forehead. Mr. Lucas remarked on the extreme rarity of the site for primary sore. In the whole course of his experience he had met with only one other on the tongue. In that case the chancre was on the right edge near the tip and corresponded to a ragged artificial tooth plate. It presented a more distinct rim than in the case shown. The man, who was between 50 and 60 years of age, had enlarged lymphatics in the submaxillary triangle and an eruption similar to that in the case shown.

Mr. ALBAN H. G. DORAN read a paper entitled "Large Bile Cyst of the Liver; Jaundice without Cholelithiasis; Incision and Drainage; Recovery." The patient was a woman, aged 42 years, who three years before admission to hospital when in the second month of pregnancy fell against a washing tub, striking the right hypochondrium; abortion occurred within a few hours. The case will be found in full at p. 1218. —Mr. W. BRUCE CLARKE said that Mr. Alban Doran had *hardly made it clear to what pathological condition the* presence of the cyst was due. He considered that the cyst was either congenital in origin or due to injury and he was inclined to favour the view that it was due to injury. He mentioned the case of a patient who was the subject of hydronephrosis and also had epilepsy. On getting out of bed [illegible] had ruptured into the hydronephrotic cyst. Similar cases of traumatic hydrone phrosis had been recorded and he thought there was no reason why a cyst should not be produced in the liver in the same way. With regard to the cause of the jaundice he was of the opinion that it depended on pressure on the duct and that the normal passage did not open till some three weeks after the operation. He did not consider that it was possible in such a case as this before operation to diagnose between a hydatid cyst, a simple cyst of the liver, and malignant disease.—Mr. A. C. BUTLER-SMYTHE referred to the difficulty of diagnosis in the present case. He had seen the patient before operation and had formed the opinion that there was [illegible] by cutting off a portion of the wall of the cyst at the time of the operation. The gall-bladder and the ducts were greatly pressed upon by the cyst and he thought that the jaundice was probably more due to mechanical obstruction than to actual obliteration of the ducts. With regard to the moveable kidney which was present on the right side he was of opinion that the right kidney could in a large majority of cases be felt in women who had had more *than one pregnancy.* He did *not consider that the administration* of chloride of calcium had much effect in preventing the occurrence of hæmorrhage.—The PRESIDENT said that he did not think it necessary to explain the persistent flow of bile into the cyst after it had been opened as due to a catarrhal condition of the duct, for he regarded the opening into the cyst as the freer passage, and it was only when the cyst began to contract that the bile resumed its original channel.—Mr. ALBAN DORAN replied.

MEDICAL SOCIETY OF LONDON.

Discussion on Purpura in Childhood.

A MEETING of this society was held on Oct. 26th, Dr. F. DE HAVILLAND HALL, the President, being in the chair.

Dr. A. F. VOELCKER opened a discussion on Purpura in Childhood. He found some difficulty in defining the term purpura, for it might be a disease, essential or idiopathic purpura, or only a symptom—symptomatic purpura. It was a condition in which hæmorrhages occurred in the skin and in and from the mucous membranes. He would limit the discussion of it to the condition as met with in the first 12 years of life. Essential purpura was by no means a common disease. At the Middlesex Hospital in ten years (1891–1900) only 36 cases had been admitted and only five of these were under ten years of age. At the Hospital for Sick Children, Great Ormond-street, out of 6465 cases admitted in six years (1897 to 1902) there had been only 16 cases of purpura. The disease was more common in the female sex. Symptomatic purpura, on the other hand, was, he believed, more common than essential purpura and more common in early life than in adults. Season had no influence in its causation. The toxic effects of certain drugs, such as potassium iodide, quinine, and ergot, were well known to be occasional causes; and among the other causal factors were whooping-cough, measles, and other acute specific fevers (when it indicated a severe toxæmia), septicæmia, and malignant endocarditis. Cases of gastro-enteritis associated with purpura were referred to and their connexion was discussed. The condition might also be associated with chronic renal disease, cardiac valvular disease, malignant disease (especially sarcoma), jaundice, leukæmia, Hodgkin's disease, hæmophilia, and rheumatism. Purpura was not at all common in scurvy or scurvy rickets. There were four recognised clinical varieties: (1) purpura simplex, where the purpuric eruption was confined to the skin; (2) purpura rheumatica, in which the joints were said to be affected; (3) purpura hæmorrhagica (morbus maculosus), in which there were hæmorrhages from the mucous membranes and severe constitutional symptoms; and (4) Henoch's purpura which was common in children, had a tendency to relapse, and to the occurrence of joint symptoms, which might be ushered in by diarrhœa, vomiting, and abdominal pain. Dr. Voelcker did not believe that there was any close or necessary relation between purpura and the rheumatic state. The former was only related to rheumatism in the same way as it was to the acute specific fevers. In regard to the treatment rest in bed was indicated. No drug appeared to have any definite controlling influence. Opium was of value for the pain and diarrhœa. Calcium chloride had been tried but without effect. It was chiefly *from epistaxis that the* fatal issue resulted and possibly suprarenal extract might be applicable for this

Dr. F. J. POYNTON regarded purpura as a symptomatic condition and said that in most cases it appeared to him to be related to a rheumatic process. Purpura was not common in his experience in the scurvy rickets of childhood. The rheumatic poison seemed to have a very definite effect on the blood-vessels as seen in cases of purpuric pericarditis and in the epistaxis which was apt to occur in rheumatic children. He believed that purpura was definitely associated with rheumatism and was dependent on the rheumatic micro-organism.

Dr. J. WALTER CARR agreed as to the rarity of so-called essential or idiopathic purpura and quoted statistics in proof. Out of six cases five were girls and one a boy. He believed that purpura was closely related to rheumatism. The cases of rheumatic purpura which died were probably registered under rheumatism. Some cases of purpura were of hæmophilic origin, as in a case which he had watched for three years. Others were undoubtedly idiopathic in the sense of having no obvious causal agent. Rest was a valuable *element in treatment.* Turpentine seemed *to* be of use sometimes.

Dr. A. E. WRIGHT regarded the pathology of purpura as a question of derangement of the balance between the blood and the blood-vessels. There was certainly a nervous influence in the process of effusion and he mentioned the case of a man who could produce an attack of urticaria at will by fixing his mind upon the subject. There were, in his view, *three varieties or degrees of effusion—serous effusion,* consisting of lymph, as in urticaria; serous hæmatomata [illegible] as in chilblains and [illegible] *the blood elements.* [illegible] Hæmophilic blood [illegible]pect to find deficient coagulation in every case of purpura but other elements of the blood might be found wanting such as serum globulin and *serum* albumin. Bacterial toxins broke down the albumins into peptones which were much less viscid. Calcium chloride would only be *of use when* the effusion depended on deficiency of lime in the blood, not in conditions such as those he had just mentioned.

The PRESIDENT remarked on the rarity of essential purpura In ten years out of 1000 in-patients at the Westminster Hospital there were only 15 cases of purpura and *only five of these* were under ten years of age. At the London Hospital (according to Sir Stephen Mackenzie) in 16 years out of 17,000 patients there were only 200 cases of purpura—49 under ten years of age. He (the President) had been particularly struck by the association of purpura with ulcerative colitis. He agreed with Dr. Voelcker in not regarding purpura as necessarily connected with rheumatism; the joint pains of the former might be mistaken for rheumatism. Sulphocarbolate of sodium in half-drachm doses every four hours had been useful in his experience but he depended mainly on turpentine.

Dr. VOELCKER replied.

CLINICAL SOCIETY OF LONDON.

Exhibition of Cases and Specimens.

A meeting of this society was held on Oct. 23rd, Dr. Frederick Taylor, the President, being in the chair.

Dr. Leonard B. Williams exhibited a case of Dercum's Disease (Adiposis Dolorosa) in a man, aged 47 years. The swellings had first appeared in the occipital region two and a half years before. There were now bilateral, more or less symmetrical, swellings distributed over the trunk and the upper arms, the face, the forearms, the legs, the hands, and the feet being free. Some of these swellings were typical lipomata; others gave the sensation of varicocele. Their development was accompanied by pain and paroxysms of pain occurred not infrequently without any obvious cause. There was a great tendency to hæmorrhages over these swellings, especially after any exercise of the underlying muscles. The patient had become progressively weaker since he came under observation two months before. There was only one other recorded case of this disease in a male.—Mr. A. A. Bowlby, C.M.G., thought that this case was less allied to the true adiposis dolorosa of Dercum than to the group of cases which Mr. W. Morrant Baker and he (Mr. Bowlby) had described in the Transactions of the Royal Medical and Chirurgical Society under the name "diffuse lipoma."[1] These latter were mostly male patients and, as in Dr. Williams's case, pain was not a pronounced feature.—Dr. Herbert S. French asked if any mental deflection or loss of bodily vigour had been observed in this patient, features which he had observed in another case of this disease.—Dr. Williams, in reply, said that although his patient had but little pain just now it had been very severe in the evolution of the malady which corresponded in other respects with Dercum's disease. The morbid change was probably a connective-tissue dystrophy, possibly secondary to neuritis. Dr. Williams suggested that the morbid condition described by Mr. Bowlby as diffuse lipoma, and that by Dercum as adiposis dolorosa, were in reality the same disease.

Mr. Thomas H. Kellock exhibited a case of Ectopia Vesicæ after operation. The patient was a boy, aged four and a half years. The operation was performed in two parts. On the first occasion, in June, 1903, the penis, which was, as usual, in a condition of entire epispadias, was dissected from its anterior attachments, drawn through an opening made through the scrotum, behind what represented the symphysis pubis, and fixed in that position by sutures. At the second operation, in August, 1903, the whole of the visible portion of the bladder was dissected up, turned down, and drawn under the arch of skin in front of the symphysis by sutures passed through its margins. All the urine now passed along the penis into the perineum, where it was hoped it would be possible to collect it in an apparatus without much inconvenience to the patient.—Mr. Kellock also exhibited a case of Possible Tumour at the Base of the Skull in a child aged two and a half years.

Dr. Herbert Tilley exhibited a case of Vascular Nasopharyngeal Fibroma arising within the left maxillary antrum removed by a combined operation through the soft and hard palate with extensive removal of the anterior wall of the left superior maxillary bone. The patient was a boy, aged 14 years, who complained of complete nasal obstruction associated with blood-stained discharge from the left nostril of five months' duration. Examination showed a large, sloughy, readily bleeding mass completely filling the left nasal fossa from the anterior to the posterior nares. Two operations were performed in November and December, 1901, and two others after extensive recurrence in March and July, 1902. Dr. Tilley wished to emphasise the value of a preliminary laryngotomy in such operations. Since the last operation there had been no recurrence, the patient had grown four inches, and early this year the soft palate had been sutured. The growth (a fibro-angioma) was also shown. Microscopically it did not appear to be malignant although it was locally recurrent.

Dr. French showed two cases of Osteitis Deformans. The first case was that of a man, aged 54 years, who presented marked thickening of both tibiæ and fibulæ with curving, kyphosis in the dorsal region, and lordosis in the lumbar region. The condition began three years before after an attack of gout. The second case was that of a woman, aged 53 years, in whom the condition had begun ten years before at the time of the menopause.—Mr. Bowlby remarked on the fact that in the woman the history showed that for six years the only evidence of disease was to be found in one bone. Sir James Paget had included one case of this kind in his original description of the disease, although most of his cases had involved many different bones.—Mr. Harold L. Barnard referred to a case he had seen of probable osteitis deformans which had apparently begun in one bone. He also asked if spontaneous fracture ever occurred in these cases.—Dr. French, in reply, referred to a case in which spontaneous fracture had occurred.

Mr. Herbert J. Paterson (introduced by Mr. Bowlby) showed a Metal Case measuring four and a half inches long and almost three-quarters of an inch in diameter which was swallowed by a man suffering from pulmonary consumption. Inside the metal case there was a glass inhaler containing a drachm of creasote. No symptoms were produced and the inhaler could not be detected by abdominal palpation, but a skiagram (which was exhibited) showed the metal case lying to the left of the vertebral column, with its long axis parallel to the spine. Mr. Paterson opened the stomach and removed the case which was lying in the œsophagus with about an inch of its length projecting into the cardiac end of the stomach. The patient made an uninterrupted recovery.

Mr. Edgar Beaumont exhibited a child, aged 14 months, with Apparent Absence of the External Sexual Organs. Micturition was performed through an orifice beneath the symphysis pubis. A cicatricial line could be seen stretching downwards from this orifice such as might be produced by the cementing together of the labia majora.—Mr. Kellock referred to the difficulties which had arisen in cases where it had not been possible to determine the sex of newly born children. The great majority of cases of such sexually abnormal children turned out to be males.

Mr. Barnard exhibited a case of Sarcoma of the Left Suprarenal Gland, with Secondary Deposits in the Cranial Bones. The patient was a male child, aged two and a half years. The illness had dated from a fall on the head six weeks before. The entire head was now enlarged and the eyes were protruding. In the left hypochondrium was a tumour probably of suprarenal origin. Apart from moderate anæmia the blood showed no marked changes.—Mr. Barnard also exhibited a soft hæmorrhagic sarcoma taken from the skull of a similar case, in which a suprarenal tumour was the only other growth in the body.—Mr. Barnard also exhibited and demonstrated a Trident for the multiple ligature of the pedicles of ovarian tumours, or omentum, an instrument which he had devised to avoid the following dangers: (1) omission of a part of the tissue; (2) confusion in tying the wrong ends; (3) uncertainty as to whether the ligatures were locked; (4) division of the tissues too near the ligature; and (5) tedious loss of time.

LIVERPOOL MEDICAL INSTITUTION.

Exhibition of Cases.—Colour Blindness.—Appendicitis.

A meeting of this society was held on Oct. 22nd, Mr. Rushton Parker, the President, being in the chair.

Mr. G. P. Newbolt showed a male patient, aged 64 years, from whom he had successfully removed a large Simple Papilloma of the Larynx involving the Right Vocal Cord. Thyrotomy was immediately preceded by tracheotomy. The tumour had been growing for six years.

Dr. Henry Briggs exhibited a Portable Metal Operating Table designed by Richelot and made by Mathieu of Paris. The Trendelenburg position of the patient was readily secured.

Dr. Thomas Bushby showed a case of Aneurysm of the Ascending Aorta in an unmarried woman, aged 26 years. The condition had existed for the past eight years.

Dr. K. A. Grossmann read a paper on the Quantitative Examination of Colour Vision from the point of view of the practical requirements of recognising colour signals. These requirements were analysed and the desirability of the examination with coloured lights was emphasised. Congenital and acquired colour blindness were considered; the former involved the whole vision field, the latter often only parts thereof. The most frequent and the most dangerous form was the defect of the fovea—central colour scotoma. It was often caused by toxic influences—e.g., by tobacco—and was infinitely more frequent than was generally assumed. Its existence was not detected by the ordinary tests, especially not with Holmgren's skeins. The exact frequency of occurrence was not known as it was rarely looked for. Dr. Grossmann then described and demonstrated his test for the examination of colour and the principles underlying its construction.—Dr. E. NICHOLSON said the greater number of cases showed simply confusion between green and drabs or dark grey, about 1 per cent. of men being thus affected. The graver form, confusion between green and red, was not more than one-tenth as common. The green-drab defect was of little consequence to seamen or railway men except in some foggy states of the air when green might be mistaken for a bright light more easily than in the case of persons with normal colour vision. For the estimation of this defect Dr. Grossmann's method promised to be most useful.

---

[1] Transactions of the Royal Medical and Chirurgical Society, vol. lxix., 1886.

Dr. W. BLAIR BELL read a paper on Some Points in the [illegible] appendicitis was preceded by a primary dilatation of the cæcum, possibly by a chronic typhlitis in most cases; it was found almost entirely in the upper classes, being due to over-eating and "bolting" of food, a state of affairs which when accompanied by constipation inevitably, unless cured, led to infection of the appendix.—Mr. F. T. PAUL said that he thought the difficulty in diagnosis was sometimes due to the variable situation of the appendix, which in one case might cause a pelvic abscess and in another an abscess in the neighbourhood of the liver. The source of the trouble was almost invariably mechanical, fæces and fæcal concretions becoming impacted in the appendix. No doubt the appendix was subject to attacks of colic and irritation in the earlier stages, but the more serious lesion, peritonitis, only occurred after the irritation had produced a stricture or the concretion a stercoral ulcer and sloughing. The milder phases of the complaint could not usually be diagnosed with absolute certainty, whilst the acute forms could always be recognised as peritonitis and as such receive appropriate treatment.—The PRESIDENT remarked that even "fulminating" cases with widespread peritoneal infiltration were not all fatal as he had experienced on several occasions, also that cases of abscess effused around the appendix and bounded by peritoneal adhesions were commonly less difficult to manage successfully than abscess occupying a retroperitoneal or retrocæcal position.

SOCIETY FOR THE STUDY OF DISEASE IN CHILDREN.—A meeting of this society was held on Oct. 16th, Mr. Clinton T. Dent being in the chair.—Mr. R. Clement Lucas related the particulars of a case of Strangulated Hernia in an infant, 28 days old, on whom he had successfully operated. Two days before coming under observation the child had been seized with a sudden screaming fit and the right side of the scrotum was then for the first time noticed to be enlarged. Persistent vomiting and constipation soon followed. At the operation the hernial sac was found to be dark-blue in colour and to contain a considerable quantity of blood-stained serous fluid, while a small knuckle of purple intestine was strangulated by the neck of the sac.—Dr. Henry Skelding (Bedford) referred to a somewhat similar case in an infant seven weeks old on whom he had recently operated. In operating he now commenced his incision from opposite the external ring and carried it outwards and upwards towards the crest of the ilium. The advantages were: (1) easier manipulation without drawing up the testis; (2) less friction on the wound by the truss; and (3) the dressings were less liable to become soiled.—Mr. J. W. Thompson Walker agreed that a diagnosis of hydrocele might be made in such cases owing to the amount of fluid in the sac, as Mr. Lucas had pointed out. He related a case in which the opposite mistake was made. A child developed a scrotal swelling accompanied by vomiting, pain, and [illegible] had been [illegible] that the c[illegible]nalis, which proved to be correct.—Mr. J. Jackson Clarke mentioned the case of a newly born infant, deeply jaundiced, who had two large scrotal herniæ and vomited frequently. One of the herniæ was easily reduced but the other was not and Mr. Clarke performed herniotomy and returned the bowel to the abdomen. The vomiting continued and the child died and on examination the condition was found to be an interruption in the small intestine at the site of Meckel's diverticulum.—Mr. J. H. Chaldecott read a paper on the Employment of Ethyl Chloride as a General Anæsthetic. He described the method of administration (preferably by Ormsby's ether inhaler): (1) in single dose cases where, after anæsthesia was induced, the mask was removed and the operation was performed without any further administration; (2) in more prolonged cases where the administration was continued during the operation; and (3) in cases in which anæsthesia was induced by ethyl chloride and continued by ether and chloroform. He claimed for ethyl chloride that it was the best anæsthetic for short operations upon the mouth, throat, and nose, and that it was very useful, especially in the case of children, as a preliminary to ether or chloroform. At the same time it was a powerful anæsthetic and the patient should be carefully prepared beforehand, as in the case of other anæsthetics.—Dr. Atwood Thorne said he had found ethyl chloride very convenient but not always without drawbacks. In two cases the patients had been insufficiently anæsthetised and in another case severe vomiting had followed, although this possibly was not due to the anæsthetic.—Mr. Sydney Stephenson said that he had had considerable experience of ethyl chloride in ophthalmic out-patient work and was more than satisfied with it. He had never witnessed any untoward symptoms and vomiting he thought was generally due to an overdose of the anæsthetic.—Dr. J. Porter Parkinson read a note on Paralytic Chorea. The patient, a boy, aged ten years, suffered from hemichorea with almost complete paralysis of the affected side, while the involuntary movements were not well marked. There was evidence of mitral disease.—Mr. Jackson Clarke read a paper on the Association of Certain Deformities with Affections of the Throat. He had come to the conclusion that hyperplasia of the adenoid tissue in the nasopharynx and throughout the body was as characteristic of rickets as the hyperplasia of the epiphyses.—Dr. C. J. Macalister (Liverpool) recorded a case of severe Gastro intestinal Catarrh in a child, aged four years. A remarkable feature of the case was the enormous distension of the abdomen, which diminished greatly during the night but recurred immediately after the first meal in the morning. Gradual improvement followed the exclusion of milk from the diet, with the employment of suitable drugs.

EDINBURGH ROYAL MEDICAL SOCIETY.—The first meeting of the 167th session of this society was held on Oct. 23rd, Dr. B. P. Watson being in the chair.—Dr. R. A. Fleming gave a lantern demonstration on Retinal Hæmorrhage and Optic Neuritis. He emphasised the diagnostic [illegible] theories regarding its causation and he strongly supported the view that the condition was a toxic one. He demonstrated the chief pathological changes and showed that these were in the neuroglia cells for the most part. He illustrated his paper by a series of beautiful slides and he also exhibited a large number of sketches and photographs demonstrating the same conditions.—Dr Shaw read, for Dr. Fitzwilliams, notes on a case of Tetanus which occurred in a farmer who received a large wound in one thigh. The symptoms were quite classical and the bacillus of tetanus was found in the wound.—Dr. T. W. E. Ross read notes on a case of Kopf-tetanus which occurred in a middle-aged man who received two slight abrasions on one temple. The symptoms developed somewhat gradually and then became very severe. The patient had frequent spasms and the case terminated fatally by failure of respiration. The case differed from cases of kopf tetanus that had been described in four respects—namely, (1) the insignificance of the wound; (2) swallowing being practically unaffected; (3) the facial paralysis coming on before the spasms; and (4) the presence of spasms in the lower extremities.

CHELSEA CLINICAL SOCIETY.—This society inaugurated the commencement of its seventh session by holding its first meeting at the new Chelsea Dispensary on Oct. 20th.—The President, Dr. T. Vincent Dickinson, who was in the chair, chose for his opening address the subject of Medical Societies and gave an interesting and amusing account of medical men and their patients.—On the conclusion of the address a very successful smoking concert took place.

BRISTOL MEDICO-CHIRURGICAL SOCIETY.—The annual meeting of this society was held on Oct. 14th.—Mr. G. Munro Smith, the President for the past session, vacated the chair to his successor, Mr. J. Paul Bush, C.M.G., who then gave an inaugural address. He chose for his subject "Some Surprises I have met with" and related many unusual occurrences and surprises that he had come across in his surgical work and during his experiences in South Africa. He gave interesting details of the working of the Princess Christian Hospital, enumerated many remarkable cases he had seen, and enlivened his address with amusing anecdotes. —Dr. R. Shingleton Smith proposed, and Mr. N. C. Dobson seconded, that the best thanks of the society should be given to Mr. Bush for his able address.—This was carried by acclamation and Mr. Bush having made a suitable reply the officers for the ensuing session were appointed.—Mr. H. F. Mole was appointed honorary secretary in place of Mr. Bush who had held the office for the past nine years.

Reviews and Notices of Books.

Vorlesungen über Kinderkrankheiten: ein Handbuch für Studirenden und Aerzte. (Lectures on the Diseases of Children: A Handbook for Students and Practitioners.) By Professor EDUARD HENOCH. Eleventh edition. Berlin: August Hirschwald. 1903. Pp. 940. Price 17 marks.

THE first edition of this book appeared in the year 1881; since then ten additional editions have been published and the sale has considerably exceeded 20,000 copies. In 1889 the fourth edition was translated by Dr. J. Thomson for the New Sydenham Society and in this way it has become familiar to English readers. During the greater portion of the time which has elapsed since its first appearance and the publication of the eleventh edition Professor Henoch's "Lectures on the Diseases of Children" has had only one serious rival to contend with—namely, Professor A. Baginsky's "Lehrbuch der Kinderkrankheiten." If we remember rightly the latter text-book was published in the year 1882—namely, one year later than the first edition of the work under review. The expansion, popularity, and scope of these two works have followed closely parallel lines and that in the past they have fulfilled the requirements of students and practitioners is abundantly testified by the large number of editions which their respective authors have been called upon to revise. We know not how it may be in Germany but we have no hesitation in saying that the days of handbooks of the character of those of Professor Baginsky and Professor Henoch are numbered, if not already over, both in this country and in America. Compare for one moment the brilliance and attractiveness of the methods of illustration, of printing, of paragraphing, and of the generous leading of the type of such works as those of Holt, Rotch, and Koplik with the deserts of monotonous printing and with the endless paragraphs which in the work before us sometimes run their unsympathetic course over many pages without headline, illustration, or diversity of type to arrest the eye and to fix the attention. In the days when there was practically no competition for the patronage of readers students were content to accept without question the educational pabulum provided by authors and to sit down to their meal of dry bones without benefit of garniture or of the gastronomic expedients which please the eye and aid digestion. In a word, Professor Henoch's lectures, which served their purpose well enough in the past, are to-day entirely out of date and unsuitable to the requirements of the modern student. In his revision the author has practically adhered to the same order and classification of disease which he adopted in the first edition; to anyone who has followed the recent advances in that branch of medicine in which the author is so justly distinguished this conservatism is somewhat perplexing. For instance, the term "atrophy" covers in these lectures a number of conditions which, from the point of view of etiology and pathology, bear no sort of relationship to one another. Simple atrophy, which is now generally known under the name of athrepsia, is not differentiated from the atrophy which is symptomatic of many wasting diseases—e.g., tuberculosis. Again, under the general heading of "Dyspepsia" a few diseases of the stomach and a large number of those referable to the bowel are differentiated. Among the latter that exceedingly common condition which in this country is generally called "acholia" or "cœliac disease" and which in Germany passes under the name of "fettdiarrhöe," is mentioned only to be dismissed, since in the author's opinion, although coming under the head of dyspepsia, it does not constitute an independent variety of the disease. However, whether acholia is an independent disease or not its practical importance warrants an independent line of treatment.

In spite of the length of the articles which are devoted to the description of the various diseases and in spite of the closeness of the print it is quite remarkable how very little definite information is provided as the result of the descriptive method adopted by the author. Although, of course, we must not lose sight of the fact that this book is a collection of lectures and not strictly of the nature of a text-book, nevertheless there is such an inextricable jumble of etiology, pathology, symptoms, treatment, and prognosis that it would be quite impossible for any reader who referred to this book for specific information to arrive at the knowledge he required without examining the whole section which deals with the disease in question. As a clinician Professor Henoch's powers of observation and discernment are undoubted and for resourcefulness in treatment he bears a similarly high reputation, but as a writer of books his want of method and system clearly condemns him. In his preface to the present edition the author remarks on the enormous amount of new literature in the field of dietetics; at the same time he regrets that the scope of his work does not permit him to do more than to refer superficially to the newer methods of feeding. Breast feeding, or when this is impossible, milk diluted with one, two, or three parts of water according to the age of the infant, he believes answers all the requirements of infant dietetics. Sterilisation of cow's milk he believes to be necessary and for this purpose he commends the Soxhlet apparatus. A recommendation for the treatment of certain acute cases of dyspepsia by cold, or even iced, milk and water deserves attention. Calomel and hydrochloric acid are the drugs in which he has most confidence in the treatment of the heterogeneous disorders which are classed under the heading of dyspepsia. In whooping-cough he thinks there is no drug like morphia. In this connexion perhaps heroin might be a safer substitute.

As a hand-book we cannot recommend this work of Professor Henoch, not only because it is dull reading and badly arranged but because it has been most inefficiently revised. Practically none of the recent work in which modern physicians are interested, such as achondroplasia, congenital rickets, lymphatism, infantilism, stenosis and spasm of the pylorus, and exact methods of infant feeding, is in any way referred to. The lectures on dentition and scrofula, perhaps, by very reason of the author's conservatism, are in our opinion among the best.

New Conceptions in Science. By CARL SNYDER. New York and London: Harper and Bros. 1903. Pp. 361. Price 7s. 6d. net.

THIS book is an American view of the relations of science and progress and one of the most interesting chapters in it is that in which the author deals with what he is constrained to call America's inferior position in the scientific world. He points out that while the educational facilities of the United States are great, yet he is not able to claim that America has produced many great men of discovery comparable with Pasteur, Lister, Koch, Clerk Maxwell, Hertz, Helmholtz, Crookes, Rontgen, van't Hoff, Ostwald, Raoult, Kelvin, Faraday, Berthelot, and others. It is refreshing to hear at any rate of this country being placed in a creditable position. "The stronghold," he says, "of English science within the last century has distinctly been the Royal Institution in Albemarle-street Thence have the most brilliant discoveries in England come." We cordially allow the author the comfort which the fact evidently affords him that the Royal Institution was founded, after all, by an American—namely, Benjamin Thompson, who was later Count Rumford, and who was born in a village near Boston. Count Rumford was a man of chequered career. He had strong scientific instincts and strong political instincts also which brought him into contact with revolutions. He finally settled in England and just a century ago, he conceived the plan of the Royal Institution. In England perhaps we have not realised what magnificent work has been done in this institution and to what great industrial developments researches like those which Faraday conducted there have led. We may well have a feeling of admiration for that institution in which, to quote one instance, the principle of the modern dynamo was discovered. In the view of the author the Royal Institution alone has done more for English science than all the English universities put together. "I should like to see, I should like to assist in," he adds, "the founding of such an institution in the chief city of the New World."

On the whole, the developments of science, including those which have been quite recently made in consequence of the discovery of radium, are adequately treated in the book under review. The author's enthusiasm, however, leads him now and then to speculate upon certain facts to a further extent than perhaps those facts warrant him in going. His writing, however, is clear, his facts are arranged in proper sequence, and he has written the story in a bright and attractive way. The man of ordinary intelligence could read the pages with advantage and on the whole we think he should get a very fair idea of the trend of present-day research and discovery. The author certainly has presented a wide field for the curious to wander through. Starting with a consideration of the facts known about the stellar universe, he proceeds to things mundane, and next to a guess as to what electricity is and as to what atoms are. The discussion of the aspects of synthetic chemistry precedes sections on "What is Life," "The Action of the Brain," "The Constitution of the Human Body," and "The Nature of Disease." Finally, he touches upon psychical science and concludes with an account of wireless telegraphy. The author has selected as a text, so to speak, on the page preceding the contents page the following observations of Sir Oliver Lodge "The ordinary run of men live among phenomena of which they care nothing and know less. They see bodies fall to the earth, they hear sound, they kindle fires, they see the heavens roll above them, but of the causes and inner workings of the whole they are ignorant and with their ignorance they are content." Mr. Snyder might have added as an appropriate postscript the seventh, eighth, and ninth verses of the fourth chapter of the second book of Esdras, which run thus: "And he said unto me, If I had asked thee saying, How many dwellings are there in the heart of the sea or how many springs are there at the fountain head of the deep? or how many ways are above the firmament? or which are the outgoings of hell? or which are the paths of paradise? peradventure thou wouldst say unto me, I never went down into the deep, nor as yet into hell, neither did I ever climb up into Heaven. Nevertheless, now have I asked thee but only of the fire and wind, and of the day, things where through thou hast passed, and without which thou canst not be, and yet hast thou given me no answer of them." Such was the great philosopher Newton's view and in spite of the wonderful "new conceptions of science" it is the view of most of her leading devotees at the present day.

Animal and Vegetable Fixed Oils, Fats, Butters, and Waxes; their Preparation and Properties. By C. R. ALDER WRIGHT, D.Sc. Lond., B.Sc. Vict., F.R.S. Second edition, edited and partly rewritten by C. AINSWORTH MITCHELL, B.A. Oxon., F.I.C. London: Charles Griffin and Co. 1903. Pp. 804. Price 25s.

THE late Dr. Alder Wright was up to the time of his death lecturer on chemistry at St. Mary's Hospital Medical School and it was well known to chemists that in the intervals of his academic work he devoted much time to the study of that interesting group of bodies—the oils, fats, and waxes. His acquaintance with the subject naturally brought him into contact with the technical applications of the bodies with which he experimented in the laboratory. It is obvious that a very wide field of technical industry is covered by the subjects dealt with in this volume. Candles, soaps, and similar products form, of course, a considerable feature of home industries, to say nothing of many other applications of oils and fats.

The first edition of the present work was issued in 1893, when the author stated that its object was to give general descriptions of the methods whereby animal and vegetable oils and fats are obtained from natural sources. Such descriptions naturally formed the introduction to an account of the leading practical applications and uses and the physical and chemical properties and reactions of these interesting and important bodies. Dr. Wright, however, stopped somewhat short of analytical methods so far as regards their application to the detection of the adulteration of oils and so chemists, though finding the work one of extreme value as a source of reference, were obliged to look elsewhere for information upon analytical details. In the second edition Mr. Ainsworth Mitchell has endeavoured to fill this gap and to render the work capable of being used as an analytical text-book and in this endeavour we feel he has done a real service to analytical chemists. The work of extension thus involved has, of course, necessitated the rewriting of certain of the chapters, whilst one chapter, dealing with the methods employed in detecting the adulteration of oils and fats, is almost entirely fresh. This step, however, has not altered the general plan of the work. Even to the reader who has no technical concern with the subject many of the chapters will be of the greatest interest. We may mention those, for example, dealing with the manufacture of soaps, candles, night-lights, and the recovery of glycerine from soap leys. Man's ingenuity in devising machines to make the manufacture of the important commodities of daily domestic use efficient and speedy is well exemplified in the machinery designed for the manufacture of candles and soap. We presume that some of the earlier methods in regard to both manufactures are now obsolete. We do not suppose, for example, that the modern dip is made in the way in which it used to be or that mottled soap has its basis in the old mottle which consisted of iron salts accidentally derived from the metallic impurities of the "black ash" which was then used for saponifying the oil. Nowadays pigments are added to give the "veined" or mottled appearance throughout the soap.

The book deals with matters of the greatest interest both to the trade and to those who are dependent upon the trade for the supply of good, well-made, and honest products. Mr. Mitchell undertook no small task in preparing a second edition of Dr. Wright's work. In this task we venture to think he has succeeded and chemists and others will readily own that he has presented them with an excellent and up-to-date edition of a standard work.

LIBRARY TABLE

Sight and Hearing in Childhood. By Robert Brudenell Carter, F.R.C.S. Eng., Consulting Ophthalmic Surgeon to St. George's Hospital, and Arthur H. Cheatle, F.R.C.S. Eng., Assistant Aural Surgeon to King's College Hospital. London: The Scientific Press, Limited. 1903. Pp. 120. Price 2*s.* net.—This little book is intended for the public and specially for parents and those engaged in the education of the youth of the country. It will serve a useful purpose if it helps to draw attention to the frequency of defective sight and hearing in childhood, if it brings home to masters the necessity of considering the recipient of teaching as well as the teaching itself, and if it guides them to look with some suspicion upon the once orthodox belief that all apt scholars are the results of the skill of the preceptor and all dunces the exponents of inherited or natural incapacity. The authors, each in his own department, have been forced to realise the heavy toll which is deducted from the possible capacities of the rising generation by defects of sight and hearing. They very rightly urge, both upon parents and upon those who manage schools, that one of the first questions to be asked about a child in relation to his school or to his intended calling is whether he can see and hear with sufficient acuteness to be safely left to take his place among a crowd. The book is both clearly and simply written. The mechanism and anatomy of vision and of hearing are described and the causes of defects, the consequences of defective vision, the aids to vision, and the cultivation of vision are in turn dealt with. In writing of the consequences of defective vision, Mr. Brudenell Carter draws attention to retinal torpidity arising from want of exercise. He suggests that the determination of the acuteness of vision and of the rapidity of perception should be made for each eye separately in the nursery, at least by the age of eight years, and remarks that in this way much subsequent disappointment would be saved. At every school the vision of each new pupil should be tested and recorded, as affording knowledge of facts absolutely essential to the proper conduct of his education. In the chapter on the Cultivation of Vision, he points out that two separate aims are to be kept in view—viz., the improvements in the acuteness and quickness of vision; these should both be cultivated by the combined effects of exercises and emulation. The cultivation of the colour sense is also a matter which should at least be attempted in every school. Mr. Cheatle's chapters on the Care of the Ears in Childhood, the Diseases of the Ear, and Diseases of the Breathing Pathway are well worth reading. The first named is one that will be helpful to all mothers and nurses.

A Pharmacopœia for Diseases of the Skin, containing Concise Formulæ, Mixtures, Ointments, Lotions, Caustics, Rules of Diet, Classification, and Therapeutical Index. Edited by James Startin, M R C S Eng., Senior Surgeon to the London Skin Hospital, Fitzroy-square Fifth edition. Bristol: John Wright and Co. 1903 Pp. 64. Price 2*s.* 6*d.* —This is a convenient little book inasmuch as it contains many useful prescriptions for affections of the skin but many of these medicines require to be used with more precaution than would be imagined from the prescriptions as they appear. The "indications" for each preparation are rather vague. The use of the symbol for a scruple is unnecessary and somewhat liable to cause confusion. There can be no object in writing Hydrargyri Ammon. Chloridi ℈ ss. and in the very next line Acid. Carbolici gr. x., as the quantities are identical. It would be far better to banish the scruple from all prescriptions.

Surgery: its Theory and Practice. By William Johnson Walsham, F.R.C.S. Eng., M.B., C.M. Aberd., Surgeon to, and formerly Lecturer on Surgery and on Anatomy at, St. Bartholomew's Hospital; Member of the Court of Examiners, Royal College of Surgeons of England, &c. Eighth edition, with 622 Illustrations, including 20 Skiagram Plates, by Walter George Spencer, M S., M.B. Lond., F.R.C S. Eng., Surgeon to the Westminster Hospital. London: J. and A. Churchill. 1903. Pp 1227. Price 18*s.* net.—The recent death of Mr. Walsham lends a sad interest to the issue of the eighth edition of this standard work. The larger share in the preparation of this eighth edition has been taken by Mr. Spencer and therefore his name appears on the title page. Even a glance at the book shows the very great changes that have been made; nearly 300 pages of text have been required to accommodate the increase of matter necessitated by the progress of surgery and a very large number of additional illustrations still further enhance the value of the work. Of "Walsham's Surgery" 38,000 copies have now been issued and the mere mention of these figures proves conclusively that this treatise has supplied what is needed. A work so extensively used is almost beyond criticism; faults, indeed, there may be but they are far outweighed by the unquestionable merits and in the present edition it is difficult to find anything to criticise. The reputation enjoyed during many generations of students will be increased and continued, we do not doubt, for many years to come. The student cannot find a book better suited to his needs and those engaged in the practice of their profession may turn with advantage to this volume for a solution of difficulties encountered. The illustrations are, on the whole, clear and good; a few of the microscopic sections are too indefinite to be of much value but we may especially commend the skiagrams which have been supplied by Dr. Hugh Walsham.

Surgical Asepsis, especially Adapted to Operations in the Home of the Patient. By Henry B. Palmer, M.D., Consulting Surgeon to the Central Maine General Hospital. With 90 Illustrations. Philadelphia: F. A Davis Company. 1903. Pp. 231. Price $1.25.—As the author mentions in his preface, the home treatment of surgical cases offers some very decided advantages over treatment at a hospital or nursing home if the same quality of nursing can be obtained and this work is intended to assist surgeons in carrying out surgical operations and treatment in private houses. It deals with the general principles of aseptic wound treatment, the means of sterilisation, the preparation of a room for operation, and the preparation of the patient. The after-treatment is also given. In a chapter on Minor Aseptic Procedures many useful little hints are to be found. We are glad to see that Dr. Palmer insists on the sterilisation of the hypodermic needle. This is a precaution which is too often neglected.

JOURNALS AND MAGAZINES.

The Practitioner.—The results of organotherapy in Addison's disease are by no means as satisfactory as are those which we confidently expect in a similar method applied to myxœdema, the disease with which this mode of treatment is most familiarly associated. Dr. E. W. Adams supplies in the October issue of the *Practitioner* an account of organotherapy as applied to Addison's disease which is comprehensive and clear Dr Adams divides the cases in regard to the results of the treatment into four classes (1) alarming or fatal result, (2) no influence, (3) marked improvement, and (4) permanent benefit. The natural tendency of the disease towards periods of abatement and temporary recovery is carefully reckoned with The whole article is of value to all those who are concerned in the study and treatment of Addison's disease A lecture on the Diagnosis of Hysteria by Dr J Purves Stewart supplies some instructive cases and is excellently illustrated by diagrams of the various forms of anæsthesia and paræsthesia occurring in this affection Dr Guthrie Rankin's practical paper upon Headache is continued in this number and is quite as full of sound observation and advice as was his last contribution on the same subject An article on the Frequency of Alimentary Glycosuria in the Children of Diabetic Persons and one upon the Relationship between Leukæmia and Tuberculosis form the other principal constituents in a capital number of the journal

The Journal of Anatomy and Physiology Conducted by SIR WILLIAM TURNER K C B, F R S, D J CUNNINGHAM, F R S, G S HUNTINGTON, M D, A MACALISTER, F R S, and J G M'KENDRICK, F R S Vol XXXVIII, Part I, October, 1903 8vo With plates and figures in the text. London Charles Griffin and Co, Limited Price 6s —The contents of this number are as follows 1 Abnormalities of the Renal Arteries with Remarks on their Development and Morphology, by Alfred H Young, M B, F R C S, and Peter Thompson, M D, with a plate showing some varieties 2. A Chemical Study of the Hibernating Gland of the Hedgehog together with the Changes it undergoes during Winter Sleep, by E W Wace Carlier, M D, and C A. Lovatt Evans The authors state that their investigation confirms the remarkable fact that life during hibernation is maintained practically upon fat alone, a condition made necessary by the well known inability of the animal body to lay up a store of nitrogen. 3 Note on an Abnormal Colon, by G Elliot Smith, M D In this case the cæcum was entirely absent and the colon was placed in one plane 4 A Discussion of some Points in Connexion with the Suprarenal Glands—Cortical and Medullary, by Swale Vincent, J Francis Mason Scholar 5 Abnormal Nasal Bones, by B Wahby, with two plates 6. The Lower Cervical Fasciæ, by J Ernest Frazer, F R C S This description of the lower cervical fasciæ, which is illustrated by several drawings, is founded on careful dissection 7 A case of Accessory Patellæ in the Human Subject, with remarks on Emargination of the Patella, by W Wright, M B, M Sc, with three woodcuts in the text. 8 On the Influence of the Patella in Extension of the Knee joint, by J Dunlop Lickley, M B, Ch B It is here shown that in addition to the patella being a lever of the first order it is an important agent in varying the leverage by altering the position of the fulcrum 9 The Unsymmetrical Kidney, its Compensatory Enlargement, by Frederick Craven Moore, M Sc, M D Vict. 10 The Germ Cells, Part I, with two plates, by John Beard D Sc 11 A case of Abnormal Arrangement of the Aortic Valves, by H K Abbott, M D This number contains the Proceedings of the Anatomical Society of Great Britain and Ireland

The Journal of Physiology Edited by SIR MICHAEL FOSTER, F R S, and J N LANGLEY, F R S Vol XXX, No 1 London C J Clay and Sons August 24th, 1903 Price 7s —The contents of this number are as follows 1 Digestion Leucocytosis in Normal and in Spleenless Dogs, by Alexander Goodall G Lovell Gulland, and D Noel Paton The chief conclusions at which they arrive will be found in THE LANCET of Oct 24th, p 1182 2 The Estimation of Potassium and Sodium in Urine and in other Material of Organic Origin, by W H Hartley, D Sc Lond, and K J P Orton, M A. Cantab 3 Reflex Pupil dilatation by Way of the Cervical Sympathetic Nerve, by H K Anderson, M D Dr Anderson finds that after section of the third nerve dilatation of the pupil may be readily excited by tactile and pathic stimuli but the dilatation ceases when the cervical sympathetic is also cut No evidence was obtained of efferent fibres to the iris except those in the third and sympathetic nerves After section of the third nerve no constriction of the pupil could be obtained either by variations of light or other sensory stimulation There was therefore no evidence of inhibition of the central sympathetic tone of the dilatator After section of the third nerve hippus may occur, the rhythmical contraction and dilatation of the pupil ceasing at once on section of the sympathetic nerve After section of the spinal cord immediately below the bulb stimulation of the central end of the sciatic nerve still causes slight dilatation of the pupil, retraction of the nictitating membrane, and separation of the eyelids 4 The Precipitation of Proteids by Alcohol and certain other Reagents, by M Christine Tebb, an interesting article on the obscure chemical reactions of the proteids of the blood, milk, eggs, and muscle. 5 The Qualitative Difference of Spinal Reflex corresponding with the Qualitative Difference of Cutaneous Stimulus, by C S Sherrington, M A, M D, F R S Professor Sherrington's observations were chiefly made upon dogs with a view of determining the causes of the "scratch reflex" in dogs He shows that in the dog different kinds of nerve endings situated in one and the same cutaneous field possess reflex spinal connexions differing wholly *inter se* 6 The Formation of Uric Acid in Birds, by T H Milroy, M D 7 The Proteolytic Activities of the Pancreatic Juice by W M Bayliss and E H Starling, F R S 8 The Products of the Proteolytic Action of an Enzyme contained in the Cells of the Kidney, with one figure in the text by H D Dakin, Exhibition Research Scholar This number also contains the Proceedings of the Physiological Society on June 27th, July 11th, and July 25th, 1903

Caledonian Medical Journal —The principal contents of the October number are two articles, both of them interesting from the historical and folklore point of view The first of these is an essay which gained one of the Stewart Celtic prizes, its subject is Highland Therapy and it was written by Mrs Robert Moodie of Edinburgh, a native of Kintail in Western Ross The second of the two articles is on the Social Life of the Scottish Gael and is by Dr J B McLaren of Salford.

Mercy and Truth —The two principal articles in the October number are (1) on the Medical Mission Meeting held at Keswick on July 24th, and (2) on the Chinese Mode of Life by the Rev M Mackenzie, M B Edin Dr Mackenzie says that the Chinese mode of life as a whole excels that of European countries, that Chinese clothing is more hygienic than that of Europeans and that opium smoking in China is a less evil than alcoholism in Europe

Dublin Journal of Medical Science —The original communications in the October number are on a case of Trigeminal Neuralgia and Excision of the Gasserian Ganglion, by Mr T W Gordon, and on the Hygienic Aspect of Flax Manufacture, by Dr H S Purdon This is also the annual "educational number" and contains a section giving full details as to medical education and examinations in Ireland

West London Medical Journal.—The principal features of the October number are two presidential addresses and the report of the council of the West London Medico Chirurgical Society presented at the annual meeting last July The presidential address delivered before the society by Dr. Seymour Taylor on Oct. 2nd is entitled "*Milestones in*

Medicine," the successive discoveries or improvements mentioned under this head being the ligature, introduced by Ambroise Paré; vaccination, introduced by Jenner; the stethoscope, introduced by Laennec; anæsthesia, introduced by Wells, Morton, and Sir James Simpson; and finally, antisepsis, introduced by Lord Lister. The retiring presidential address delivered by Mr. Rickard W. Lloyd dealt with the administration of anæsthetics in rectal diseases. A lengthy abstract of this address appeared in THE LANCET of July 11th, p. 102.

Looking Back.

FROM

THE LANCET, *SATURDAY*, OCT. 29, 1825.

MIDDLESEX HOSPITAL.

To the Editor of THE LANCET.

SIR,—As it is your professed object to direct your attention to every species of corruption connected with public Hospitals, I beg to call your attention to the proceedings of the Weekly-board and Surgeons of Middlesex Hospital. The circumstances of a poor surgery-man being dismissed and prosecuted with relentless rigour, for imitating a superior servant of that institution, by *drawing a few teeth* from a deceased patient, must be within the recollection of your readers. In that case, investigation immediately followed, and the unprotected man was brought to the gates of a prison, where however, fortunately, the matter terminated. Lord Robert Seymour, who has been so great a benefactor to the institution, will, I trust, explain to the public the proceedings in question.

If there be a law against removing *any part* of the body of a dead patient, Mr. Bell has been guilty of a violation of it, and is as much entitled to punishment as the person alluded to; if, on the contrary, no such law exist, why prosecute an under servant, while his superior is permitted to promote his interest or gratification with impunity? This species of legislation verifies the language of the satyrist, when he said "Laws are like cobwebs, which catch small flies, but suffer the great ones to break through them."

I trust you will continue to furnish your readers with reports from this Hospital, which are of inestimable value, not only to students, but to individuals in practice. The operations performed by Joe Burns and John Shaw, or the senior and junior Joes as they are called, will, no doubt, excite that interest which the labours of such distinguished persons cannot fail to produce. The operation of amputation below the knee, by *young* Joe, which required *an hour and ten minutes* for its performance, and the particulars of the long-looked-for operation of lithotomy, by the same person, together with the appearances upon dissection *nine hours afterwards** will no doubt be acceptable to your readers.

Permit me, in conclusion, Sir, to congratulate you on the extensive circulation of THE LANCET, and the success attending its operations.

I am, Sir,
Yours truly,
OBSERVER.

---

* In consequence of the length of Mr. Lawrence's lecture, and of the review, we have been under the necessity of postponing the account of the above operations, as well as several articles of interest, to our next number.—ED.

SOME NOVEL PATENTS.—An American inventor has patented an apparatus for the treatment of defective hearing. It contains a bellows, two electro-magnets, and several other parts; the object of it is "to set up air impulses in the air-tube" and "to produce electric impulses either separately from, or in conjunction with, the air movements." Another inventor has patented a toy for expanding the lungs. It consists of four glass flasks, partly filled with fluid and connected by a system of tubes. Descriptions and drawings of both these contrivances are given in the *Official Gazette* of the United States Patent Office issued on Oct. 13th.

THE ENTRIES AT THE MEDICAL SCHOOLS.

BY the kindness and courtesy of the deans and secretaries of the various medical schools and colleges of the metropolis and the provinces we are able to give our readers some idea of the number of individuals who have entered upon the study of medicine in the autumn session of the present year. It will be seen that while in the provinces there has been a general fall in the number of entries as compared with those of last year the London schools show a slight increase. From the University of Birmingham we have received no returns. The clerk to the medical faculty of that University, on the instruction of the dean, informs us that "pursuant to the custom adopted during the past few years no statistics will be issued respecting entries." The figures for the University of Oxford must be taken as approximate. There is at present no means of finding out at this University how many freshmen intend ultimately to read medicine, for it is not until they take anatomy and physiology that they become collected together. A fair approximation can, however, be obtained by taking the number of men who began dissection during the past year which was 28. The total number of men reading medicine at present at the University of Oxford is probably 150 or 160. This approximation is obtained by multiplying the average number of men studying medicine at each college, which is eight, by the number of colleges, which is 21.

ENTRIES FOR THE YEAR 1903–04.

London.

THE LANCET.

LONDON: SATURDAY, OCTOBER 31, 1903

The Etiology of Human Tuberculosis.

SINCE the dramatic pronouncement made in 1901 by Professor KOCH to the effect that bovine tuberculosis bore no causal relation to human tuberculosis and that therefore it was unnecessary to take any precautions against the consumption of tuberculous meat or against milk drawn from tubercle-riddled udders we have heard nothing to equal in importance the address on tuberculosis which was delivered by Professor BEHRING at the recent Congress of German Naturalists and Medical Men. A summary of this remarkable delivery was published in THE LANCET of Oct. 24th (p. 1199) and to this we must refer our readers for the details At the present moment we propose to review briefly the general position. The attitude taken up by Professor KOCH in 1901 was eminently lucid and simple. As the result of a series of experiments carried out by himself and Professor SCHÜTZ it had not been found practicable in the opinion of the experimenters to infect bovine and certain other animals with tubercle of human origin, and from these experiments, as also from arguments as to the rarity of primary intestinal tuberculosis, Professor KOCH seems to have inferred that the converse held good—i.e., that bovine tuberculosis could not be communicated to the human species. Since that date a large number of somewhat similar experiments have been made and their general trend has been to show that the results by no means always correspond with those obtained by Professor KOCH and Professor SCHÜTZ. Recent work shows in fact that tubercle of human origin can, at any rate under certain conditions, be transmitted to bovines. This being so, the followers of Professor KOCH, in so far as they base their case upon the negative experiments above referred to, are placed somewhat upon the horns of a dilemma Either they must discredit the recent positive experiments or, for the sake of logical consistency, they must infer that bovine tuberculosis is transmissible to the human species. But whichever horn of the dilemma is selected the only point which is really left over for discussion and experiment at the present time is the *facility* with which human tuberculosis can be transmitted to the bovine host, and as to this, as also with respect to the inferences which are to be drawn from such facility, the report of the Royal Commission on Tuberculosis must be awaited.

In the meantime, however, there comes, also from Germany, another pronouncement, which is, in effect, the absolute antithesis of the position taken up by Professor KOCH and his followers. Professor KOCH having pronounced the opinion that it was not advisable to take any measures against bovine tuberculosis threw his world-wide influence in the direction of combating the infection from person to person and he went so far as to express the opinion that the remarkable decline of pulmonary tuberculosis in this country was very largely the result of the "special hospitals for tubercular patients in England." As to this point, as also with respect to the decrease of the disease elsewhere than in England, the recent Milroy Lectures on Pulmonary Tuberculosis, by Dr. H. T. BULSTRODE, which were published in the columns of THE LANCET,[1] should be consulted. But in diametrical opposition to the thesis of personal infection, which in our view has been materially over-rated, we now find Professor BEHRING expressing the opinion that communication of pulmonary tuberculosis to adults by contagion has not yet been demonstrated. Shortly summed up, Professor BEHRING'S attitude is somewhat as follows. For the development of tuberculosis the soil as well as the seed is essential, and looking at the wide distribution of the parasite the former is, perhaps, more important than the latter. For instance, Professor NAEGELI claims to have shown that among the necropsies made at the Pathological Institute of Zürich signs of tuberculosis were found in every instance in the bodies of persons over 30 years of age and Dr. FRANZ, an Austrian army medical officer, states that 68 per cent. of the men in an Austrian regiment reacted positively to the tuberculin test. Professor BEHRING'S fundamental proposition is, in fact, that as a general rule tuberculosis has its origin in early infancy and that, contrary to the view of Professor KOCH, the vehicle for the conveyance of this latent infection is milk. The cause of active tuberculosis is not therefore so much exposure to infection as the conditions of life which alter the soil of the individual already the bearer of the essential seed. Infants are prone to absorb the tubercle bacillus, not only by reason of tuberculous milk, but also, and mainly, from the fact that the permeability of the gastro-intestinal canal of young animals as shown by the experiments of Dr. ROMER, one of Professor BEHRING'S pupils, is much greater than is that of adults. Professor BEHRING is evidently impressed by a belief that what may be termed "vaccination" against tuberculosis is not beyond the realms of practicability and hence that sanatoriums and other therapeutic measures may become unnecessary. However, the discrepancy that at present obtains between the two German professors upon the fundamental question results, we fear in something approaching an administrative *impasse* and we cannot altogether suppress a belief that the very wide generalisations which have in each instance been drawn from a single series of experiments were not fully justified in a scientific sense. An entirely different theory is that propounded by Dr. H. CHARLTON BASTIAN in an article which we publish in another column. His views will be considered highly heterodox by the majority of living pathologists and bacteriologists, for he boldly suggests that tuberculosis can be produced *de novo*. He bases his conclusions on the conditions respectively known as "Davaine's septicæmia" and "Pasteur's septicæmia" and the experiments of Sir JOHN BURDON SANDERSON who demonstrated that a form of septicæmia (similar to that of PASTEUR) could be set up by injecting a small quantity of a germ-free chemical irritant into the peritoneal cavity or into the subcutaneous tissue of a rabbit. The ingenious yet scientific arguments upon which he founds this assumption can be studied by our readers in the original paper. In another leading article we refer to the opinions held by Professor HUEPPE as expressed in the Harben Lectures.

Reverting to the views of Professor KOCH and Professor BEHRING, we consider it judicious to await the report of the Royal Commission on Tuberculosis before we throw in our lot either with the extremists who believe that tuberculosis may be "stamped out" by sanatoriums alone or with those whose opinion it is that the only danger of infection resides in tuberculous milk. The value of sanatoriums as curative agents cannot, of course, be questioned and all humanitarians will welcome their extension in this sense, but their value as preventive agents depends, firstly, upon the precise degree of the communicability of pulmonary tuberculosis; secondly, upon the extent to which they can be used as educational agencies in promoting resistance generally; and, lastly, upon how far "drop infection" can be prevented or reduced, as also upon the percentage of patients who are sent out from the sanatoriums with no tubercle bacilli in their sputum. Professor KOCH regarded this absence of tubercle bacilli "as the only sure test of success, especially as regards prophylaxis," and he added that "about 20 per cent. of the patients who have tubercle bacilli in their sputum lose them by the treatment" in sanatoriums. Fortunately, administrative action has in the past been taken, though nearly unconsciously, in the direction of promoting the resistance of the host and the harvest, estimated in the enormous reduction in the death-rate from pulmonary tuberculosis, has already been largely gathered in. Whether, therefore, in the end it will be the thesis of Professor KOCH or the thesis of Professor BEHRING which will be found to be true, or whether, as is not improbable, each will have to be regarded as containing something of the truth, the work done by medical officers of health will continue to reduce the death-rate from tuberculosis.

◆

The Harben Lectures.

THE Harben Lectures were this year delivered before the Fellows of the Royal Institute of Public Health by Professor FERDINAND HUEPPE of the University of Prague. These lectures (of which short abstracts will be found at p. 1216 of our present issue), in due course, will be fully reported in the society's official journal and we strongly advise all those who are interested in the subjects which they embrace to avail themselves of the opportunity which will thus be afforded of studying the views and conceptions held by one of the broadest-minded, most erudite, and most philosophic investigators among bacteriologists of to-day. The specific titles of the lectures in which Professor HUEPPE embodied many of his most important views were as follows: (1) General Views on the Etiology of Infectious Diseases; (2) Hygiene and Serum Researches; and (3) Tuberculosis.

It is not, however, so much our purpose to provide a *résumé* of these lectures as to describe in general the influence which Professor HUEPPE has undoubtedly exercised on our conceptions of the general biological processes involved in the manifestation of disease. In the opinion of many of those who watch scientific events there are at the present time in Europe two men who more than any others are welding together and weaving into homogeneous relationship many of the scattered and tangled strands of scientific knowledge in its relationship to pathology and to bacteriology. These two men are Professor VERWORN of Jena University and Professor HUEPPE of Prague. It has been the task of these two investigators in their respective and complementary fields of study to apply the general laws of conservation of energy and of organic evolution to the understanding of the normal and abnormal processes of the human body; and by the application of inductive and deductive methods of reasoning both of them have been enabled to anticipate on theoretical grounds certain facts in bacteriology and general physiology which have since been confirmed by actual experiment.

At the Congress of Naturalists at Nuremberg in the year 1893 Professor HUEPPE first publicly propounded his views on the causation of disease, adopting for the first time in the history of medicine a clear and unambiguous nomenclature. He claimed, though at that time his audience hardly appreciated his arguments, that the *causes* of all diseases were prefigured in the molecular structure of the cell—in the potential energies of protoplasm,—and that these potential energies could become converted into kinetic energies (symptoms) under the influence of disease stimuli. The clear definition of the meaning of causes, of stimuli, and of resistances in his terminology has enabled Professor HUEPPE to formulate a definite and unambiguous interpretation of disease and to clear the ground of many of the misconceptions which have arisen from erroneous and contradictory deductions arising out of VIRCHOW'S "Cellular Pathology," out of PASTEUR'S and KOCH'S "Conception of the Specificity of Pathogenic Bacteria," and out of PETTENKOFER'S claim that time and place were the chief determining factors in the production of disease. In this memorable lecture Professor HUEPPE maintained that the essence of disease lay not in the cell, in the bacterium, or in the circumstances of time and place, but that disease should rather be expressed as the function of the sum of all these constituent factors. He further insisted that the manifestation of disease was the expression of the conversion into kinetic energy of potential energy residing in the molecular structure of the cell under the liberating influence of disease stimuli and under the influence of varying conditions in the environment. The Harben Lectures were made the occasion by Professor HUEPPE for the circumstantiation by means of concrete examples of the theoretical views which he propounded in 1893. The adaptation of cell activities to the changing conditions of environment and the variation of bacterial species in accordance with the circumstances of time and place were illustrated by examples of susceptibility to, and immunity from, tuberculosis and other diseases and by the morphological and metabolic variations of the tubercle bacillus itself in its varying conditions of parasitism in different hosts. The full appreciation of Professor HUEPPE'S philosophic conceptions throws unmistakeable light on many of the biological problems which vex the minds of medical controversialists to-day.

As far as prevention of disease is concerned, in Professor HUEPPE'S opinion, the task which now lies before hygienists is to arrive at an understanding of the processes by which a susceptibility to disease may be converted into an immunity and to determine the nature of the resistances which hinder the release of what may be called pathological energy; in other words, to study the disposition of men to disease and the methods by which it may be favourably influenced by suitable external conditions.

◆

The Relation of Chemistry to Medicine: A Retrospect.

SCIENCE nowadays has many branches and happily it is rarely that a decidedly progressive step is made in one branch which does not in some way advance the general cause. The history of medicine certainly teaches that such is the case. Empirical methods give way to rational treatment as the principles of the collateral sciences upon which, after all, medicine must be based are further elucidated. Historically defined as an art medicine is now rapidly establishing its claims to be considered a science. At one time, of course, there was considerable incredulity that assistance could ever come to medicine through such channels as chemistry and physics and the practitioner of a century ago could not trace a very intimate connexion between contemporary medical advance and the growth of chemical knowledge. An interesting example of this scepticism was published in our columns last week under the heading of "Looking Back." "Chemistry," said Dr. CLUTTERBUCK, in a lecture on the Theory and Practice of Physic delivered in the theatre of the General Dispensary, Aldersgate street, and published in THE LANCET of Oct. 22nd, 1825, "notwithstanding the vast advances it has made of late years, and the important applications that have been made of it in other arts, has still but a remote relation to medical science. It is of no service to us in regard to physiology; it does not offer an explanation that is altogether satisfactory of any one of the functions of the animal œconomy." Doubtless Dr. CLUTTERBUCK was well within the mark in these statements made 78 years ago when of necessity empiricism in medicine largely, though, of course, not entirely, prevailed. It may be that the world went very well then but it was yet to see a SIMPSON, a PASTEUR, a HUXLEY, a LISTER, and other great pioneers of medical knowledge and to gain by their devoted energies and genius a wider glimpse into the nature of things, thereby adding immensely to the relief of suffering humanity. It is not a little difficult to realise in this year of grace what the position of medicine really was in the absence of any specific knowledge as to the chemistry of the body, of nerve tissue, of the respiratory processes, of the secretions, of metabolism, of nutrition, of fermentation, of bacteriological function, of antitoxins, of organo-therapeutic agencies, and so on. Incidentally, it may be remarked also that Dr. CLUTTERBUCK spoke before chloroform was discovered and years before its application as an anæsthetic had been tried with those beneficial results which subsequent medical and surgical history has eloquently set forth. "Chemistry," however, he commenced his lecture by saying, "will make a part of this course (the materia medica) because it is chiefly of importance in its relation to pharmacy." No medical man can dispute the valuable rôle of pharmacy in medicine but surely few would hold now that the importance of chemistry to medicine rests chiefly upon its pharmaceutical applications. We must recognise that the germ theory of disease arose out of an investigation into the chemistry of fermentation—an investigation by which chemistry proved to be the foundation of bacteriology. Further, the high level to which the study of bacteriology has raised pathology is patent. The discovery of the existence of toxin and antitoxin was the highly important outcome of the study of specific pathogenic organisms and the relation between toxin and antitoxin, at one time regarded as a physiological one, is now considered to be of the nature of a chemical reaction similar to that which exists between an acid and an alkali. We are thus brought in touch with the nature of the action of a poison and in the future we may confidently hope that chemistry will explain the exact effect of poisons on the human organism and as knowledge is gained on this point so surely will the means of preventing and treating disease be strengthened.

Chemistry and physics have undoubtedly shed considerable light on the nature of disease because they have afforded an insight into the working of the parts of the human machine, for it is obvious that physiology could not have advanced far without the application of physical and chemical knowledge; the phenomena of metabolism and nutrition would not have been understood as they are at the present moment had not chemical and physical researches been prosecuted with such praiseworthy energy and skill. In Dr. CLUTTERBUCK'S time the phenomena of destructive and reparative processes were ill understood and analysis was then little advanced, while synthesis was, comparatively speaking, unknown. "We see," he said, "the same blood carried to the liver and kidneys and we find separated from it by the action of these organs in the one case bile, in the other urine; but neither bile nor urine are to be found in the common mass of blood nor can we extract them from it by any art of chemistry." The secretion of bile as an important factor in alimentation is understood, while chemistry has taught us that urine is the channel by which waste excretory products of the body are discharged. It was soon after Dr. CLUTTERBUCK delivered his interesting address, which no doubt was in complete harmony with prevailing views that urea was obtained by an artificial process, was built up entirely from inorganic elements, and so a crystalline substance identical with the urea of urine was produced by a process in which so-called "vital force" played absolutely no part. This discovery was the death-blow to the theory held in Dr. CLUTTERBUCK'S time that many things could only be the product of life processes. The art of synthesis has progressed enormously since then and not only has it given rise to that numerous class of bodies of pharmacological importance and known as synthetics, but it has also given us a clearer insight into the constitution of complex substances, a glimpse into their molecular architecture, and this added knowledge has to some extent explained the manner of the building up and breaking down of complex structures in the human physiology. Again, pharmacology, as it deals with the relation between the chemical composition and constitution of a substance and its physiological action, will no doubt prove to be the basis of rational therapeutics depending upon the administration of drugs.

Chemical research permeates in many directions and not the least important direction is that in which it relates to the nature of the processes of digestion, comprising the assimilation of starches, fats, and proteids. We know broadly the chemistry of the changes by which food is brought into a condition in which it is appropriated by the body and we know the destiny of these food substances and their bearing upon the nature of the waste products. The action of pepsin, pancreatin, and lipase are now recognised as chemical in kind. This most interesting group of bodies—the enzymes—would appear to be unorganised entities and their behaviour falls into a line with that of other chemical agents; their conduct in effecting metabolic transformations, as, for instance, the conversion of starch into sugar, appears to be due to their alternate power of giving and taking, after the manner of the oxygen-carrying substance—the hæmoglobin of the blood. There seems, again, to be little doubt that the recent developments of chemical and physical research in regard to the nature of solution and of chemical reactions in solution will throw considerable light upon physiological problems and will add materially to our knowledge of the function of fluids in the human body. The theory of the dissociation of salts in solution into "ions" is calculated to place a new interpretation upon the manner in which not only the digestive juices act but also upon the changes sustained by the blood during respiration and in the metabolic processes.

In spite of all the enormous advances, however, that have been made since Dr. CLUTTERBUCK'S time, particularly in regard to the chemistry, physics, and physiology of the processes upon which the existence and well-being of the human body depend, it must be admitted that we are a long way, a very long way, from the finality of things. But the knowledge which has accrued in this direction since the foundation of this journal and which it is our privilege to place before our readers, should serve as an encouragement to all those who study medicine and who realise what noble ends their labours have in view. Few have time to study chemical science in its entirety and the busy practitioner in particular has usually little chance of gaining further insight than broad principles will give him, but he will be ready to acknowledge that chemistry and the related sciences have extricated medicine from much empiricism, and that they will do yet more there can be little doubt.
